Biodiversitas

Novelty:

(state your claimed novelty of the findings versus current knowledge)

This study highlights several findings, such as species of arthropods found in freshwater swamp paddy in South Sumatera, Indonesia; species diversity; and abundance of arthropods inhabiting canopy of paddy treated with overdoses bioinsecticides of *Beauveria bassiana* are higher than those on the rice treated with commercial insecticide (abamectin). We also found that the overdoses bioinsecticide of *B. bassiana* did not decrease the abundance of non-target species (natural enemy of insect pests), but could decrease the herbivore insect (insect pests) population and the correct dosage for suppressing the insect pest abundance by not decreasing the abundance and diversity of non-target species is 2 L.ha⁻¹.

Statements:

This manuscript has not been published and is not under consideration for publication to any other journal or any other type of publication (including web hosting) either by me or any of my co-authors.

Author(s) has been read and agree to the Ethical Guidelines.

Manuscript received: 20 January 2020. Revision accepted: 2020

Abstract. Bioinsecticides have been shown to reduce insect pest populations, but it is necessary to monitor the impact of bioinsecticide overdoses on non-target arthropods because they are abundant in rice fields. This study aimed to analyze the impact of bioinsecticide overdoses of *B. bassiana* on species diversity and abundance of non-target arthropods. Bioinsecticides derived from *Beauveria bassiana* were sprayed on the paddy every two weeks until the harvest, at a dose of 1, 2, 3, 4 L.ha⁻¹, control (without insecticide), and abamectin as prescribed. The abundance of spiders and predatory arthropods did not decrease when bioinsecticides were applied but the abundance of spiders, especially Lycosidae and Salticidae dropped significantly when abamectin was applied. The abundance of the parasitoid decreased significantly when abamectin was applied but the abundance of parasitoids applied by bioinsecticide was not significantly different from those of control. The abundance of insect pests started to decrease when bioinsecticide was applied to 2, 3 or 4 L.ha⁻¹. The diversity species of non-target arthropods (spiders, predatory arthropods, and parasitoids) tended to decrease when it was applied bioinsecticides 3 and L.ha⁻¹ or abamectin, but their abundance remained high and no species dominance was found. For this reason, the correct dosage for suppressing insect pests abundance by not decreasing the abundance and diversity of non-target species is 2 L.ha⁻¹ and applied when herbivore abundance is high.

Key words: abamectin, parasitoids, insect pests, predatory arthropods, spiders

Running title: *Beauveria* impact on not targeted arthropods

INTRODUCTION

Freshwater swamps are wetland ecosystems that are flooded with river water or rain throughout the year. The duration of puddle in freshwater swamps depends on the typology of the land, namely deep, rather deep, and shallow. The swamp typology is generally inundated for most of the year (October to July), rather deep swamps are inundated from November to June, and shallow swamps are inundated from November to April. When lands are inundated, smallholders generally underutilize their lands. Herlinda et al. (2018) state that the smallholders start to grow paddy in April or no later than July. They generally grew once a year (Herlinda et al. 2018; Lakitan et al. 2019). Therefore, the land productivity and cropping intensity were low (Lakitan et al. 2019).

Increasing land productivity needs to be conducted carefully and sustainably because freshwater swamps are fragile ecosystems (Lakitan et al. 2019; Siaga et al. 2019). The efforts of increasing land productivity were started by business farmers by regulating water management and damming/canalization of land covering an area of between 250 and 500 ha so that they can increase the intensity of rice planting from once a year to two or three times a year. However, according to Herlinda et al. (2019a) the increase of planting intensity caused business farmers to start applying intensive and scheduled synthetic insecticides. In order to maintain a sustainable agriculture, it is necessary to introduce business farmers and smallholders the bioinsecticide which is relatively environmentally friendly and safe for rice products.

Bioinsecticides made from entomopathogenic fungi, such as *Beauveria bassiana*, have been proven to be effective in controlling various species of insect pests. *B. bassiana* can kill paddy insects such as brown plant hoppers (BPH) (Li et al. 2014; Sumikarsih et al. 2019), *Spodoptera litura* (Ayudya et al. 2019). The research results in the laboratory proved that *B. bassiana* did not harm the natural enemies of BPH (non-target arthropods) (Firouzbakht et al. 2015; Gholamzadeh-Chitgar et al. 2017). However, caution is needed in applying the bioinsecticide because the non-target arthropod species is very abundant, rich, and diverse in the paddy ecosystem of freshwater swamps in South Sumatra, such as spiders (Herlinda et al. 2018), predatory insects, parasitoids, and neutral insects (Herlinda et al. 2019b; Karenina et al. 2019) if an overdose

49 can affect the abundance and diversity of non-target arthropods. This study aimed to analyze the impact of bioinsecticide
50 overdoses of *B. bassiana* on species diversity and abundance of non-target arthropods.

51 MATERIALS AND METHODS

52 This research has been carried out in the village of Pelabuhan Dalam, Pemulutan Subdistrict, Ogan Ilir District, South
53 Sumatra, which is a center of freshwater swampy rice. The research site is surrounded by a paddy monoculture of ± 800
54 ha, which is generally planted from April or May to September or November each year. The field experiment was carried
55 out from April to September 2018, and then the arthropods samples were taken and identified in the laboratory from
56 October 2018 to March 2019. Paddy cultivation methods followed the pattern carried out by the smallholders but this
57 study used certified Mekongga varieties with purple label and planting system of "Jajar legowo" 2:1 with a spacing of
58 $50 \times 25 \times 12.5 \text{ cm}^3$. The area of each treatment plot was $38 \times 20 \text{ m}^2$ which was repeated 3 times (total 2280 m^2) where the
59 distance between plots was 10 m.

60 Preparation of land and paddy seedlings

61 Preparation of land and rice planting began with tillage, seeding, planting and maintaining of paddy. Land management
62 was conducted using mini plows and mashed using hoes. After the soil was processed, manure with a dose of $1 \text{ ton} \cdot \text{ha}^{-1}$
63 was mixed into the treated soil. The paddy seeds were first soaked with water for 24 h, and then the seeds were planted
64 using a "samir" system. The varieties used were certified with purple labels and a dose of $50 \text{ kg} \cdot \text{ha}^{-1}$. After the seedlings
65 were 5 days old, the seeds were moved into shallow rice fields and waited until they reached 14 days old. Then, the 14-
66 day-old seedlings were transplanted in the fields.

67 Paddy planting and maintenance

68 The paddy planted with a 2:1 "jajar legowo" system with the plant spacing of $50 \times 25 \times 12.5 \text{ cm}^3$. The number of
69 seedlings planted is 2-3 stems per hole. The maintenance was carried out by mechanical weeding using sickles. The water
70 management used pumping. The fertilization used liquid compost extract at a dose of $1 \text{ L} \cdot \text{ha}^{-1}$ per two weeks from the age
71 of 2 weeks to cooked milk. The making of liquid compost extraction was carried out by means of 2 L of microbial culture
72 of remodel mixed with 200 L of water, 10 kg of manure, 2 kg of NPK fertilizer, and 2 kg of phosphate fertilizer and
73 fermented for 1-2 weeks.

74 The producing of bioinsecticides and their applications

75 Bioinsecticides applied in this study were made from conidia *B. bassiana* with a carrier material of compost shrimp
76 shell and the making of the compost extract used the method of Suwandi et al. (2012). As a bioinsecticide stabilizer, 30%
77 sucrose (w/v) volume of bioinsecticide and 1% (v/v) vegetable oil were added. Conidia *B. bassiana* was propagated in
78 SDA media using the method of Safitri et al. (2018). After that, it was cultured in liquid media (SDB) incubated and
79 shaken on a shaker for 7 days. This liquid culture was added to liquid compost extract as a carrier and stabilizer of sucrose
80 and vegetable oil. This bioinsecticide was first stored for 1 month before being applied in paddy and the bioinsecticide
81 conidia density was at least $1 \times 10^9 \text{ conidia} \cdot \text{mL}^{-1}$.

82 Bioinsecticide was applied in the afternoon around 5 p.m. to prevent the death of conidia due to the ultraviolet light
83 during the day. The doses used were 1, 2, 3, 4 $\text{L} \cdot \text{ha}^{-1}$, control (without treatment), a commercial insecticide (abamectin).
84 The spraying began when the paddy reached 14, 28, 42, 56, 70, 84 days old after the transplanting (DAT).

85 Sampling arthropods in paddy

The sampling of arthropods in paddy was carried out using insect nets (sweep nets or nets) using the method of
Weilhoefer et al. (2017). The arthropods sampling was conducted 1x24 h after spraying the bioinsecticide in the morning
around 6.00-7.00 am. The sampling was carried out in the morning when the arthropods were not very active so that the
data obtained were more valid. The arthropods were taken as many as 5 nets whose scattered positions were taken in the
plot and repeated three times. The study design used a randomized group design. The arthropod sampling was carried out
when the paddy reached 15, 29, 43, 57, 71, 85 DAT. The arthropods samples were then taken to the laboratory for sorting,
cleaning, and then put in vial bottles containing 70% alcohol. The arthropods were identified by referring to the source
textbooks of Kalshoven (1981), McAlpine et al. (1987), and Barrion and Litsinger (1995)

86 Data analysis

The data on the number of individuals of each arthropod species from each treatment were used to analyze species
abundance and diversity. The abundance of arthropods during one paddy planting season was compared between the
treatments using ANOVA assisted by the Software Program of SAS University Edition 2.7 9.4 M5. The species diversity
was analyzed using the Shannon-Wiener (H') index, dominance (D), and Evenness (E) using the Magurran handbook
(Magurran 1988). The grouping data were based on guilds, namely predators (spiders and predatory insects), parasitoids,

herbivores, and neutral insects displayed in graphical forms. The non-target guilds were focused on predators (spiders and predatory insects) and parasitoids.

87

RESULTS AND DISCUSSION

88 **The arthropods species in paddy applied with bioinsecticide**

89 Predatory species found in this study were grouped into spiders and predatory insects. During one paddy planting
90 season, all spider species were found as many as 31 species (Table 1). The dominant spider species found include *Pardosa*
91 *birmanica*, *Pardosa patapatensis*, *Pardosa pseudoannulata*, *Pardosa pullata*, *Pardosa sumatrana*. The number of species
92 found in each bioinsecticide dose showed a tendency, the higher the dose the more the number of found species decreased.
93 The number of spider species dropped dramatically in plots at 4 L.ha⁻¹ and abamectin. In addition to spiders, other
94 predators were predatory insects found during one paddy planting season as many as 20 species (Table 2). The dominant
95 predatory insects which were found were *Micrapis inops*, *Verania lineata*, *Ophionea nigrofasciata*, and *Paederus fuscipes*.
96 The number of species found decreases with increasing doses of bioinsecticide and the application of abamectin. The
97 number of spider species dropped dramatically in plots at 3 and 4 L.ha⁻¹ and abamectin.

98 All parasitoids species found were 12 species (Table 3). The dominant parasitoids species were found, among others
99 *Gonatocerus ashmeadi*, *Netomocera minuta*, *Snellenius manilae*, *Xanthopimpla punctata*. The number of species found
100 showed a decrease in bioinsecticide plots at a dose of 4 L.ha⁻¹ and abamectin. The lowest number of parasitoid species was
101 found in the abamectin plot, which was only 3 species (*Helorus anomalipes*, *Pteromalus* sp., and *Stictopisthus* sp.).

102 All found species of herbivores were 22 species (Table 4). The dominant herbivores species were found, among others
103 *Leptocorisa acuta*, *Nephotetix virescens*, *Spodoptera litura*, *Nilaparvata lugens*, *Pelopidas mathias*. The number of herbivores
104 species found in plots applied with bioinsecticide doses of 3 and 4 L.ha⁻¹ and abamectin was lower than those applied with
105 bioinsecticide doses of 1 and 2 L.ha⁻¹, and control (without insecticide). All found species of neutral insects were 5
106 species (Table 5). The found species of neutral insects were *Chironomus plumosus*, *Tipula maxima*. The number of species
107 found in each treatment showed an almost equal number of 4-5 species. Figure 1 showed some arthropods found in this
108 study.

109 **Abundance of arthropods in paddy applied with bioinsecticide**

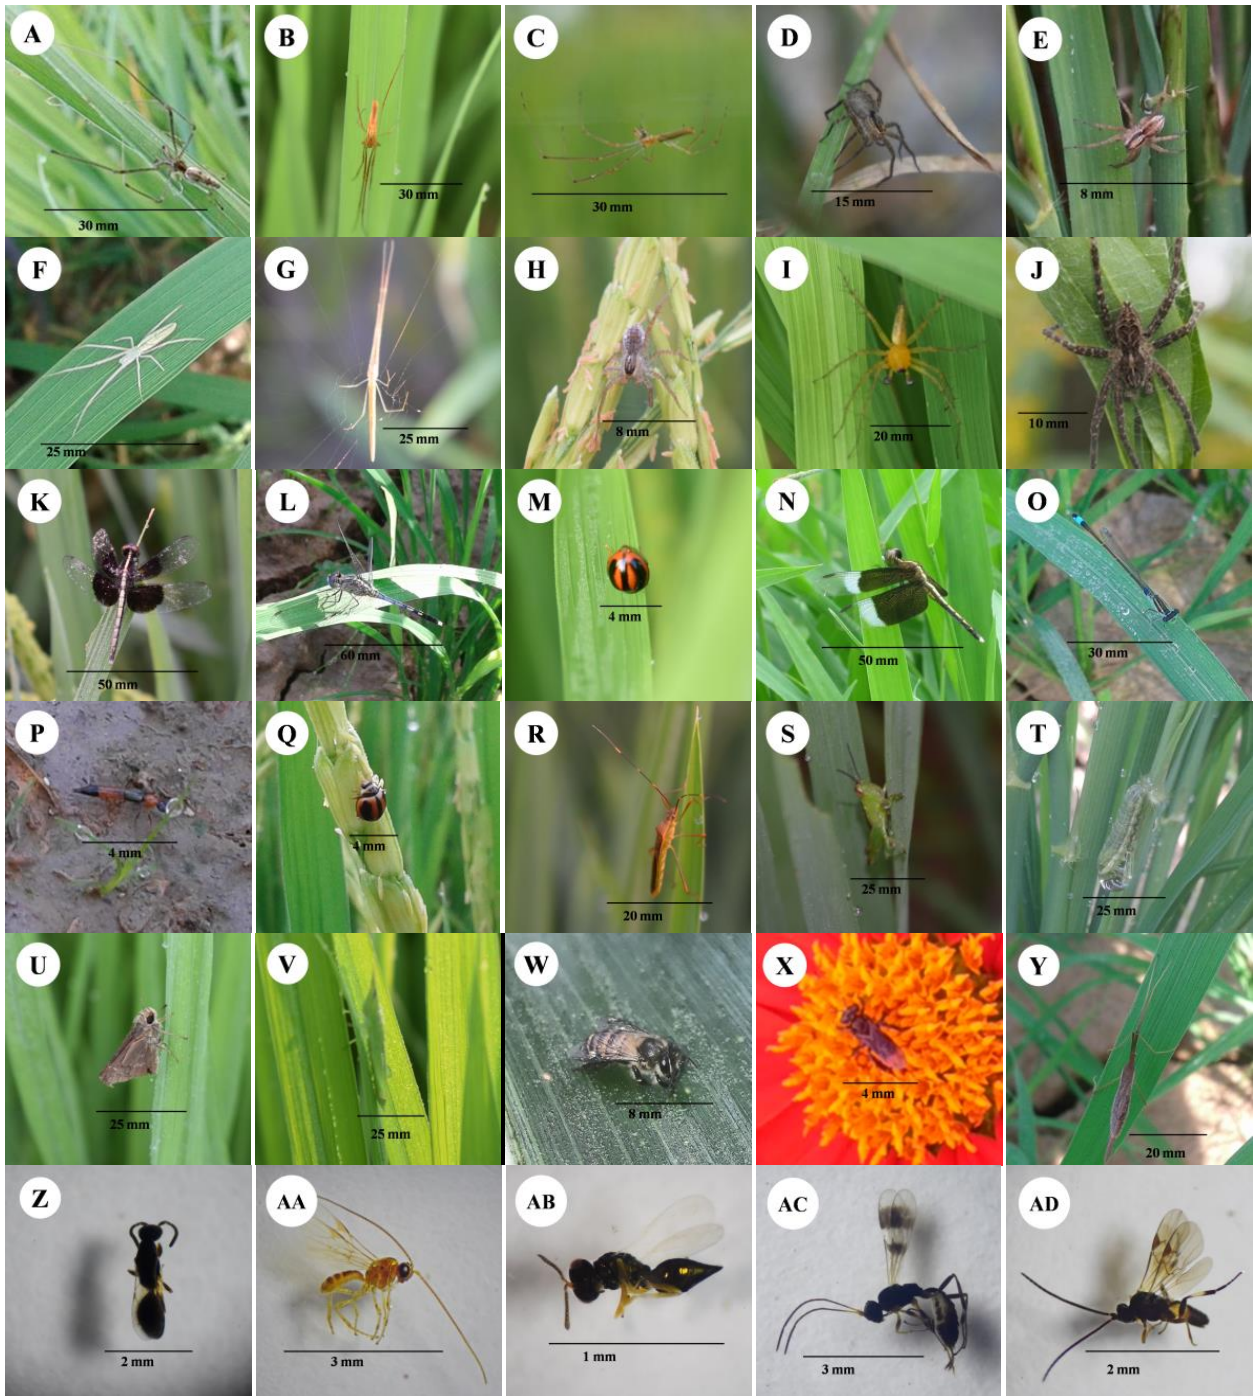

110 The total data of the abundance of predators consisting of spiders and predatory insects showed that the spider
111 abundance significantly decrease in total abundance of all species on plots applied with abamectin; yet, on plots applied
112 with bioinsecticide doses of 1-4 L.ha⁻¹ and control without insecticide there was no significant decrease in total spider
113 abundance (Table 1). A decrease in total abundance in one family was due to the application of abamectin found in
114 Lycosidae and Salticidae. The abundance of predatory insects did not decrease in the plots applied with bioinsecticide,
115 abamectin, and control (Table 2).

116 The parasitoid abundance of Hymenoptera order decreased significantly when abamectin was applied but the parasitoid
117 abundance applied with bioinsecticide was not significantly different from that of the control (Table 3). The lowest
118 abundance of parasitoids was found in the plot which was applied with abamectin, only one was found during one paddy
119 planting season.

120 The abundance of herbivores in plots applied with bioinsecticide and abamectin decreased significantly when
121 compared to those of the controls (Table 4). From the bioinsecticide field, there were found *Pelopidas mathias* larvae
122 parasitized by *B. bassiana* (Figure 2). The families significantly decreased of abundance were Noctuidae (*Spodoptera*
123 *litura*) and Acrididae. The abundance of *Spodoptera litura* decreased when the bioinsecticide dose was applied 2 L.ha⁻¹ and
124 it was not significantly different from the dose of 3 and L.ha⁻¹. Therefore, the dosage of bioinsecticide 2 L.ha⁻¹ was able to
125 reduce the abundance of *S. litura*.

126 The neutral insects which were insects that did not act as herbivores or natural enemies of herbivores did not
127 experience a decrease in total abundance in the bioinsecticide, abamectin, and control plots, but the Diptera order
128 decreased its abundance in the plots applied with bioinsecticide and abamectin (Table 5). There were 5 species of neutral
129 insects found in this study generally acting as pollinators, organic matter-decomposer, and an alternative prey for spiders.

130 Based on the comparison of abundance among the guilds (predators, parasitoids, herbivores, and neutral insects) the
131 abundance of all guilds in plots applied with abamectin tended to be lower compared to control plots and bioinsecticides
132 (Figure 3). The abundance of neutral insects and parasitoids from the beginning of planting to before harvest is always
133 lower than other guilds. The most ideal abundance of predators was shown to be much higher than the that of herbivores
134 (predator's main prey) on control plots and plots applied with doses of 1 and 2 bioinsecticides, whereas in plots doses of 3
135 and 4 L.ha⁻¹ and abamectin abundance of predators drastically decreased in herbivores abundance as well. Thus, the
136 bioinsecticide in doses of 3 and 4 L.ha⁻¹ and abamectin in addition to reducing the abundance of herbivores reduced the
137 abundance of arthropods that were not targeted (predator).

Characteristics of the arthropods community in paddy with bioinsecticide application

The species diversity (on average) was higher for spiders found in control plots applied with bioinsecticide in doses of 1 and 2 L.ha⁻¹ compared to bioinsecticide plots of 3 and 4 L.ha⁻¹ and abamectin (Table 6); still, the domination of spider species was not found in all plots. The decreased diversity of species predatory insects began to occur in plots applied with bioinsecticide in doses of 2, 3, and 4 L.ha⁻¹ and abamectin (Table 7). The lowest diversity of predatory insect species was found in the abamectin plot.

Parasitoid species diversity (on average) decreased in plots applied with bioinsecticide doses of 2, 3 and 4 L.ha⁻¹ and abamectin (Table 8). In all plots there were no species domination found. On the contrary, the diversity of herbivores species (on average) was higher in the plots applied with bioinsecticide doses of 3 and 4 L.ha⁻¹. However, in all of these plots there was no domination of herbivores species (Table 9). The decrease in diversity of species neutral insects was found in the plots applied with bioinsecticides in doses of 2, 3, 4 L.ha⁻¹ and abamectin; yet, no species dominance was found (Table 10). In addition, the abundance of neutral insects in all plots was lower than the abundance of other guilds.

230 Discussion

231 The abundance of spiders and predatory arthropods did not decrease when bioinsecticides derived from *B. bassiana*
232 were applied. The spiders and predatory arthropods were more resistant to *B. bassiana* and proved that *B. bassiana* did not
233 adversely affect the predator. Many studies suggest that *B. bassiana* is a specific fungus that only kills insects from certain
234 orders, such as Lepidoptera (Safitri et al. 2018; Ayudya et al. 2019) or Homoptera (Sumikarsih et al. 2019), whereas
235 predators found in this study were spiders and insects of the order Coleoptera and Odonata, not those of the Order
236 Lepidoptera or Homoptera. Entomopathogenic fungi are generally harmless to spiders (Yuliani 2016) and Coleoptera
237 (Ngin et al. 2017). Gholamzadeh-Chitgar et al. (2017), even when adding the *B. bassiana* they did not harm the brown
238 plant hopper predator, a predatory bug (*Andrallus spinidens*) of the Hemiptera Order.

239 The abundance of spiders, especially Lycosidae and Salticidae, decreased significantly when applied with commercial
240 insecticides from the active ingredient abamectin. The data were in line with the research results of Prabawati et al. (2019)
241 who found that spider abundance dropped significantly when paddy was sprayed with abamectin. Abamectin is a broad
242 spectrum insecticide that can kill many species of arthropods (Ananiev et al. 2002). In addition, the abundance of the
243 Hymenoptera parasitoid also decreased significantly when abamectin was applied. Sasmito et al. (2017) reported that
244 abamectin could reduce the ability of the brown planthopper parasitoid (*Anagrus nilaparvatae*) in parasitizing and also
245 reduced the abundance of these parasitoid offspring.

246 The abundance of herbivores started to decrease when applied with bioinsecticides of 2, 3 or 4 L.ha⁻¹, but at doses of 3
247 or 4 L.ha⁻¹ the diversity of species of non-target arthropods (predators and parasitoids) began to decrease. Consequently,
248 the ideal dose to reduce the abundance of herbivores which are insect pests of paddy is 2 L.ha⁻¹ and spraying is conducted
249 when the abundance of predators and parasitoids is low. Herbivores decreased in abundance after bioinsecticides derived
250 from *B. bassiana* were applied; and the herbivores found in this study included *N. lugens*, *P. mathias*, *Spodoptera litura*.
251 Herbivores found to be attacked by *B. bassiana* in the field were *P. mathias* and *S. litura* and both belonged to the
252 Lepidoptera Order.

253 The ill Lepidoptera larvae found in the bioinsecticide plot were shown to show characteristics that were attacked by *B.*
254 *bassiana*. Caterpillars were found hanging on the tips of paddy leaves and their bodies were dry, hard, and stiff. The
255 ventral abdomen was covered with white mycelia. This sick caterpillar did not smell. The fungus from the sick caterpillar
256 after being isolated and grown on PDA media resulted in a white colony and conidia growing in a round shape and hyaline
257 color. The fungal morphological features found were in accordance with the results of identification of *B. bassiana* by
258 Humber (2005) stating that mycelia of *B. bassiana* arises from the exoskeleton of insects and covers all parts of the
259 integument surface so that the insect bodies are visibly white, reverse pale to yellow colony, hyaline or colorless, 1-celled,
260 and globular and conidia, and insulated hypha. The characteristics of *P. mathias* larvae attacked by *B. bassiana* were the
261 same as those of insects (*N. lugens*) attacked by *B. bassiana* which, according to Sumikarsih et al. (2019), the body is dry,
262 hard, stiff, and odorless and from the insect's body appears a white mycelia.

263 Although the data of the abundance of non-target arthropods (spiders, predatory arthropods, and parasitoids) did not
264 decrease when overdosed bioinsecticide was applied, their species diversity tended to decrease when applied with
265 bioinsecticide doses of 3 and 4 L.ha⁻¹ or abamectin. This decrease resulted from the reduced number of species that
266 survived in plots applied with bioinsecticide doses of 3 and 4 L.ha⁻¹ or abamectin. The highest decrease in the number of
267 species was found in the plot applied with abamectin. Some species of non-target arthropods got sensitive to abamectin
268 applications, namely species of web-building spiders and Carabidae (Prabawati et al. 2019), parasitoids (*Anagrus*
269 *nilaparvatae*) (Sasmito et al. 2017). In this study the spider species sensitive to high doses of bioinsecticides (3 and 4 L.ha⁻¹)
270 were *Camaricus formosus*, *Oxyopes matiensis*, while the predatory arthropods included *Ischnura senegalensis*, *Libellula*
271 *luctuosa*, *Ortetrum Sabina*. The spider species sensitive to abamectin were The spider species sensitive to abamectin were
272 *Camaricus formosus*, *Tetragnatha maxillosa*, *Oxyopes matiensis*, *Pardosa birmanica*, *Pardosa patapatensis*, *Pardosa*
273 *pullata*, while the predatory arthropods were *Libellula* sp., *Neurothemis fluctuans*, *Ortetrum sabina*, *Ortetrum testaceum*,
274 *Mantis religiosa*, *Conocephalus longipennis*

275 Neutral insects of the Diptera order decreased in abundance in the plots applied with abamectin. Although they were
276 neutral for plants, they were important in the agro-ecosystem for alternative prey to the generalist predators (spiders).
277 According to Settle et al. (1996), neutral insects can maintain the existence of generalist predators when in the fields under
278 a condition without herbivores. In this study, a decrease in abundance was found in the Diptera Order by abamectin.
279 Therefore, abamectin in addition to reducing the abundance of spiders, predatory arthropods, reduced the abundance of
280 neutral insects and showed that the abamectin was broad-spectrum (Ananiev et al. 2002).

281 The results of this study conclude that bioinsecticide *B. bassiana* of doses of 3 and 4 L.ha⁻¹ once in two weeks has an
282 impact on reducing the number of non-target arthropods species (spiders, predatory arthropods, and parasitoids), but
283 bioinsecticides *B. bassiana* has no impact to the abundance of spiders, predatory arthropods, and parasitoids. The ideal
284 dosage to reduce the abundance of paddy insect pests (herbivores) is 2 L.ha⁻¹. For this reason, the right dose to suppress the
285 abundance of paddy insect pests by not decreasing the abundance and diversity of non-target species is 2 L.ha⁻¹.
286 Bioinsecticide spraying should be carried out when the abundance of insect pests is high, while the abundance of predators
287 and parasitoids is still low in the fields so that spraying does not have an impact on decreasing the abundance and diversity
288 of non-target arthropod species.

289 ACKNOWLEDGEMENTS

290 Thank you to the sponsor of this research, the Master Thesis Research (Penelitian Tesis Magister) program, Directorate
291 of Research and Community Service (DRPM), Directorate General of Research and Development, Kemenristekdikti, with
292 contract number: 096/SP2H/LT/DRPM/IV/2019. This research was chaired by Siti Herlinda.

Impact of bioinsecticide overdoses of *Beauveria bassiana* on species diversity and abundance of not targeted arthropods in South Sumatra freshwater swamp paddy

Manuscript received: 20 January 2020. Revision accepted: 2020

Abstract. Bioinsecticides have been shown to reduce insect pest populations, but it is necessary to monitor the impact of bioinsecticide overdoses on non-target arthropods because they are abundant in rice fields. This study aimed to analyze the impact of bioinsecticide overdoses of *B. bassiana* on species diversity and abundance of non-target arthropods. Bioinsecticides derived from *Beauveria bassiana* were sprayed on the paddy every two weeks until the ripening stage, at a dose of 1, 2, 3, 4 L.ha⁻¹, control (without insecticide), and abamectin as prescribed. The abundance of spiders and predatory arthropods did not decrease when bioinsecticides were applied but the abundance of spiders, especially Lycosidae and Salticidae dropped significantly when abamectin was applied. The abundance of the parasitoid decreased significantly when abamectin was applied but the abundance of parasitoids applied by bioinsecticide was not significantly different from those of control. The abundance of insect pests started to decrease when bioinsecticide was applied to 2, 3 or 4 L.ha⁻¹. The diversity species of non-target arthropods (spiders, predatory arthropods, and parasitoids) tended to decrease when it was applied bioinsecticides 3 and 4 L.ha⁻¹ or abamectin, but their abundance remained high and no species dominance was found. For this reason, the correct dosage for suppressing insect pests abundance by not decreasing the abundance and diversity of non-target species is 2 L.ha⁻¹ and applied when herbivore abundance is high.

Key words: abamectin, parasitoids, insect pests, predatory arthropods, spiders

Running title: *Beauveria* impact on not targeted arthropods

INTRODUCTION

Freshwater swamps are wetland ecosystems that are flooded with river water or rain throughout the year. The duration of puddle in freshwater swamps depends on the typology of the land, namely deep, rather deep, and shallow. The swamp typology is generally inundated for most of the year (October to July), rather deep swamps are inundated from November to June, and shallow swamps are inundated from November to April. When lands are inundated, smallholders generally underutilize their lands. Herlinda et al. (2018) state that the smallholders start to grow paddy in April or no later than July. They generally grew once a year (Herlinda et al. 2018; Lakitan et al. 2019). Therefore, the land productivity and cropping intensity were low (Lakitan et al. 2019).

Increasing land productivity needs to be conducted carefully and sustainably because freshwater swamps are fragile ecosystems (Lakitan et al. 2019; Siaga et al. 2019). The efforts of increasing land productivity were started by business farmers by regulating water management and damming/canalization of land covering an area of between 250 and 500 ha so that they can increase the intensity of rice planting from once a year to two or three times a year. However, according to Herlinda et al. (2019a) the increase of planting intensity caused business farmers to start applying intensive and scheduled synthetic insecticides. In order to maintain a sustainable agriculture, it is necessary to introduce business farmers and smallholders the bioinsecticide which is relatively environmentally friendly and safe for rice products.

Bioinsecticides made from entomopathogenic fungi, such as *Beauveria bassiana*, have been proven to be effective in controlling various species of insect pests. *B. bassiana* can kill paddy insects such as brown plant hoppers (BPH) (Li et al. 2014; Sumikarsih et al. 2019), *Spodoptera litura* (Ayudya et al. 2019). The research results in the laboratory proved that *B. bassiana* did not harm the natural enemies of BPH (non-target arthropods) (Firouzbakht et al. 2015; Gholamzadeh-Chitgar et al. 2017). However, caution is needed in applying the bioinsecticide because the non-target arthropod species is very abundant, rich, and diverse in the paddy ecosystem of freshwater swamps in South Sumatra, such as spiders (Herlinda et al. 2018), predatory insects, parasitoids, and neutral insects (Herlinda et al. 2019b; Karenina et al. 2019) if an overdose can affect the abundance and diversity of non-target arthropods. This study aimed to analyze the impact of bioinsecticide overdoses of *B. bassiana* on species diversity and abundance of non-target arthropods.

MATERIALS AND METHODS

This research has been carried out in the village of Pelabuhan Dalam, Pemulutan Subdistrict, Ogan Ilir District, South Sumatra, which is a center of freshwater swampy rice. The research site is surrounded by a paddy monoculture of ± 800 ha, which is generally planted from April or May to September or November each year. The field experiment was carried out from April to September 2018, and then the arthropods samples were taken and identified in the laboratory from October 2018 to March 2019. Paddy cultivation methods followed the pattern carried out by the smallholders but this study used certified Mekongga varieties with purple label and planting system of "Jajar legowo" 2:1 with a spacing of

50x25x12.5 cm³. The area of each treatment plot was 38x20 m² which was repeated 3 times (total 2280 m²) where the distance between plots was 10 m.

Preparation of land and paddy seedlings

Preparation of land and rice planting began with tillage, seeding, planting and maintaining of paddy. Land management was conducted using mini plows and mashed using hoes. After the soil was processed, manure with a dose of 1 ton.ha⁻¹ was mixed into the treated soil. The paddy seeds were first soaked with water for 24 h, and then the seeds were planted using a "samir" system. The varieties used were certified with purple labels and a dose of 50 kg.ha⁻¹. After the seedlings were 5 days old, the seeds were moved into shallow rice fields and waited until they reached 14 days old. Then, the 14-day-old seedlings were transplanted in the fields.

Paddy planting and maintenance

The paddy planted with a 2:1 "jajar legowo" system with the plant spacing of 50x25x12.5 cm³. The number of seedlings planted is 2-3 stems per hole. The maintenance was carried out by mechanical weeding using sickles. The water management used pumping. The fertilization used liquid compost extract at a dose of 1 L.ha⁻¹ per two weeks from the age of 2 weeks to **milky stage**. The making of liquid compost extraction **used the method of Suwandi et al. (2012)** was carried out by means of 2 L of microbial culture of remodel mixed with 200 L of water, 10 kg of manure, 2 kg of NPK fertilizer, and 2 kg of phosphate fertilizer and fermented for 1-2 weeks. **The liquid compost extract containing *Trichoderma virens* was used for plant nutrition.**

The producing of bioinsecticides and their applications

Bioinsecticides applied in this study were made from conidia *B. bassiana* with a carrier material of compost shrimp shell and the making of the compost extract used the method of Suwandi et al. (2012). As a bioinsecticide stabilizer, 30% sucrose (w/v) volume of bioinsecticide and 1% (v/v) vegetable oil were added. Conidia *B. bassiana* was propagated in SDA media using the method of Safitri et al. (2018). After that, it was cultured in liquid media (SDB) incubated and shaken on a shaker for 7 days. This liquid culture was added to liquid compost extract as a carrier and stabilizer of sucrose and vegetable oil. This bioinsecticide was first stored for 1 month before being applied in paddy and the bioinsecticide conidia density was at least 1 x 10⁹ conidia.mL⁻¹.

Bioinsecticide was applied in the afternoon around 5 p.m. to prevent the death of conidia due to the ultraviolet light during the day. The doses used were 1, 2, 3, 4 L.ha⁻¹, control (without treatment=0 L.ha⁻¹), a commercial insecticide (abamectin). The spraying began when the paddy reached 14, 28, 42, 56, 70, 84 days old after the transplanting (DAT). **Abamectin is an biological insecticide with broad-spectrum activity (Ananiev et al. 2002) and this product was chosen in this research due to farmers in Indonesia often using it to control a brown planthopper (BPH), *Nilaparvata lugens*.**

Sampling arthropods in paddy

The sampling of arthropods in paddy was carried out using insect nets (sweep nets) using the method of Weilhoefer et al. (2017). The arthropods sampling was conducted 1x24 h after spraying the bioinsecticide in the morning around 6.00-7.00 am. The sampling was carried out in the morning when the arthropods were not very active so that the data obtained were more valid. The arthropods were taken as many as 5 nets whose scattered positions were taken in the plot and repeated three times. The study design used a randomized group design. The arthropod sampling was carried out when the paddy reached 15, 29, 43, 57, 71, 85 DAT. The arthropods samples were then taken to the laboratory for sorting, cleaning, and then put in vial bottles containing 70% alcohol. The arthropods were identified by referring to the source textbooks of Kalshoven (1981), McAlpine et al. (1987), and Barrion and Litsinger (1995)

Data analysis

The data on the number of individuals of each arthropod species from each treatment were used to analyze species abundance and diversity. The abundance of arthropods during one paddy planting season was compared between the treatments using ANOVA assisted by the Software Program of SAS University Edition 2.7 9.4 M5. The species diversity was analyzed using the Shannon-Wiener (H') index, dominance (D), and Evenness (E) using the Magurran handbook (Magurran 1988). The grouping data were based on guilds, namely predators (spiders and predatory insects), parasitoids, herbivores, and neutral insects displayed in graphical forms. The non-target guilds were focused on predators (spiders and predatory insects) and parasitoids.

RESULTS AND DISCUSSION

The arthropods species in paddy applied with bioinsecticide

Predatory species found in this study were grouped into spiders and predatory insects. During one paddy planting season, all spider species were found as many as 31 species (Table 1). The dominant spider species found include *Pardosa birmanica*, *Pardosa patapatensis*, *Pardosa pseudoannulata*, *Pardosa pullata*, *Pardosa sumatrana*. The number of species

found in each bioinsecticide dose showed a tendency, the higher the dose the more the number of found species decreased. The number of spider species dropped dramatically in plots at 4 L.ha⁻¹ and abamectin. In addition to spiders, other predators were predatory insects found during one paddy planting season as many as 20 species (Table 2). The dominant predatory insects which were found were *Micrapis inops*, *Verania lineata*, *Ophionea nigrofasciata*, and *Paederus fuscipes*. The number of species found decreases with increasing doses of bioinsecticide and the application of abamectin. The number of spider species dropped dramatically in plots at 3 and 4 L.ha⁻¹ and abamectin.

All parasitoids species found were 12 species (Table 3). The dominant parasitoids species were found, among others *Gonatocerus ashmeadi*, *Netomocera minuta*, *Snellenius manilae*, *Xanthopimpla punctata*. The number of species found showed a decrease in bioinsecticide plots at a dose of 4 L.ha⁻¹ and abamectin. The lowest number of parasitoid species was found in the abamectin plot, which was only 3 species (*Helorus anomalipes*, *Pteromalus* sp., and *Stictopisthus* sp.).

All found species of herbivores were 22 species (Table 4). The dominant herbivores species were found, among others *Leptocorisa acuta*, *Nephotetix virescens*, *Spodoptera litura*, *Nilaparvata lugens*, *Pelopidas mathias*. The number of herbivores species found in plots applied with bioinsecticide doses of 3 and 4 L.ha⁻¹ and abamectin was lower than those applied with bioinsecticide doses of 1 and 2 L.ha⁻¹, and control (without insecticide). All found species of neutral insects were 5 species (Table 5). The found species of neutral insects were *Chironomus plumosus*, *Tipula maxima*. The number of species found in each treatment showed an almost equal number of 4-5 species. Figure 1 showed some arthropods found in this study.

Abundance of arthropods in paddy applied with bioinsecticide

The total data of the abundance of predators consisting of spiders and predatory insects showed that the spider abundance significantly decrease in total abundance of all species on plots applied with abamectin; yet, on plots applied with bioinsecticide doses of 1-4 L.ha⁻¹ and control without insecticide there was no significant decrease in total spider abundance (Table 1). A decrease in total abundance in one family was due to the application of abamectin found in Lycosidae and Salticidae. The abundance of predatory insects did not decrease in the plots applied with bioinsecticide, abamectin, and control (Table 2).

The parasitoid abundance of Hymenoptera order decreased significantly when abamectin was applied but the parasitoid abundance applied with bioinsecticide was not significantly different from that of the control (Table 3). The lowest abundance of parasitoids was found in the plot which was applied with abamectin, only one was found during one paddy planting season.

The abundance of herbivores in plots applied with bioinsecticide and abamectin decreased significantly when compared to those of the controls (Table 4). From the bioinsecticide field, there were found *Pelopidas mathias* larvae parasitized by *B. bassiana* (Figure 2). The families significantly decreased of abundance were Noctuidae (*Spodoptera litura*) and Acrididae. The abundance of *Spodoptera litura* decreased when the bioinsecticide dose was applied 2 L.ha⁻¹ and it was not significantly different from the dose of 3 and L.ha⁻¹. Therefore, the dosage of bioinsecticide 2 L.ha⁻¹ was able to reduce the abundance of *S. litura*.

The neutral insects which were insects that did not act as herbivores or natural enemies of herbivores did not experience a decrease in total abundance in the bioinsecticide, abamectin, and control plots, but the Diptera order decreased its abundance in the plots applied with bioinsecticide and abamectin (Table 5). There were 5 species of neutral insects found in this study generally acting as pollinators, organic matter-decomposer, and an alternative prey for spiders.

Based on the comparison of abundance among the guilds (predators, parasitoids, herbivores, and neutral insects) the abundance of all guilds in plots applied with abamectin tended to be lower compared to control plots and bioinsecticides (Figure 3). The abundance of neutral insects and parasitoids from the beginning of planting to before harvest is always lower than other guilds. The most ideal abundance of predators was shown to be much higher than the that of herbivores (predator's main prey) on control plots and plots applied with doses of 1 and 2 bioinsecticides, whereas in plots doses of 3 and 4 L.ha⁻¹ and abamectin abundance of predators drastically decreased in herbivores abundance as well. Thus, the bioinsecticide in doses of 3 and 4 L.ha⁻¹ and abamectin in addition to reducing the abundance of herbivores reduced the abundance of arthropods that were not targeted (predator).

Characteristics of the arthropods community in paddy with bioinsecticide application

The species diversity (on average) was higher for spiders found in control plots applied with bioinsecticide in doses of 1 and 2 L.ha⁻¹ compared to bioinsecticide plots of 3 and 4 L.ha⁻¹ and abamectin (Table 6); still, the domination of spider species was not found in all plots. The decreased diversity of species predatory insects began to occur in plots applied with bioinsecticide in doses of 2, 3, and 4 L.ha⁻¹ and abamectin (Table 7). The lowest diversity of predatory insect species was found in the abamectin plot.

Parasitoid species diversity (on average) decreased in plots applied with bioinsecticide doses of 2, 3 and 4 L.ha⁻¹ and abamectin (Table 8). In all plots there were no species domination found. On the contrary, the diversity of herbivores species (on average) was higher in the plots applied with bioinsecticide doses of 3 and 4 L.ha⁻¹. However, in all of these

plots there was no domination of herbivores species (Table 9). The decrease in diversity of species neutral insects was found in the plots applied with bioinsecticides in doses of 2, 3, 4 L.ha⁻¹ and abamectin; yet, no species dominance was found (Table 10). In addition, the abundance of neutral insects in all plots was lower than the abundance of other guilds.

Discussion

The abundance of spiders and predatory arthropods did not decrease when bioinsecticides derived from *B. bassiana* were applied. The spiders and predatory arthropods were more resistant to *B. bassiana* and proved that *B. bassiana* did not adversely affect the predator. Many studies suggest that *B. bassiana* is a specific fungus that only kills insects from certain orders, such as Lepidoptera (Safitri et al. 2018; Ayudya et al. 2019) or Homoptera (Sumikarsih et al. 2019), whereas predators found in this study were spiders and insects of the order Coleoptera and Odonata, not those of the Order Lepidoptera or Homoptera. Entomopathogenic fungi are generally harmless to spiders (Yuliani 2016) and Coleoptera (Ngin et al. 2017). Gholamzadeh-Chitgar et al. (2017), even when adding the *B. bassiana* they did not harm the brown plant hopper predator, a predatory bug (*Andrallus spinidens*) of the Hemiptera Order.

The abundance of spiders, especially Lycosidae and Salticidae, decreased significantly when applied with commercial insecticides from the active ingredient abamectin. The data were in line with the research results of Prabawati et al. (2019) who found that spider abundance dropped significantly when paddy was sprayed with abamectin. Abamectin is a broad spectrum insecticide that can kill many species of arthropods (Ananiev et al. 2002). In addition, the abundance of the Hymenoptera parasitoid also decreased significantly when abamectin was applied. Sasmito et al. (2017) reported that abamectin could reduce the ability of the brown planthopper parasitoid (*Anagrus nilaparvatae*) in parasitizing and also reduced the abundance of these parasitoid offspring.

The abundance of herbivores started to decrease when applied with bioinsecticides of 2, 3 or 4 L.ha⁻¹, but at doses of 3 or 4 L.ha⁻¹ the diversity of species of non-target arthropods (predators and parasitoids) began to decrease. Consequently, the ideal dose to reduce the abundance of herbivores which are insect pests of paddy is 2 L.ha⁻¹ and spraying is conducted when the abundance of predators and parasitoids is low. Herbivores decreased in abundance after bioinsecticides derived from *B. bassiana* were applied; and the herbivores found in this study included *N. lugens*, *P. mathias*, *Spodoptera litura*. Herbivores found to be attacked by *B. bassiana* in the field were *P. mathias* and *S. litura* and both belonged to the Lepidoptera Order.

The ill Lepidoptera larvae found in the bioinsecticide plot were shown to show characteristics that were attacked by *B. bassiana*. Caterpillars were found hanging on the tips of paddy leaves and their bodies were dry, hard, and stiff. The ventral abdomen was covered with white mycelia. This sick caterpillar did not smell. The fungus from the sick caterpillar after being isolated and grown on PDA media resulted in a white colony and conidia growing in a round shape and hyaline color. The fungal morphological features found were in accordance with the results of identification of *B. bassiana* by Humber (2005) stating that mycelia of *B. bassiana* arises from the exoskeleton of insects and covers all parts of the integument surface so that the insect bodies are visibly white, reverse pale to yellow colony, hyaline or colorless, 1-celled, and globular and conidia, and insulated hypha. The characteristics of *P. mathias* larvae attacked by *B. bassiana* were the same as those of insects (*N. lugens*) attacked by *B. bassiana* which, according to Sumikarsih et al. (2019), the body is dry, hard, stiff, and odorless and from the insect's body appears a white mycelia.

Although the data of the abundance of non-target arthropods (spiders, predatory arthropods, and parasitoids) did not decrease when overdosed bioinsecticide was applied, their species diversity tended to decrease when applied with bioinsecticide doses of 3 and 4 L.ha⁻¹ or abamectin. This decrease resulted from the reduced number of species that survived in plots applied with bioinsecticide doses of 3 and 4 L.ha⁻¹ or abamectin. The highest decrease in the number of species was found in the plot applied with abamectin. Some species of non-target arthropods got sensitive to abamectin applications, namely species of web-building spiders and Carabidae (Prabawati et al. 2019), parasitoids (*Anagrus nilaparvatae*) (Sasmito et al. 2017). In this study the spider species sensitive to high doses of bioinsecticides (3 and 4 L.ha⁻¹) were *Camaricus formosus*, *Oxyopes matiensis*, while the predatory arthropods included *Ischnura senegalensis*, *Libellula luctuosa*, *Ortetrum Sabina*. The spider species sensitive to abamectin were The spider species sensitive to abamectin were *Camaricus formosus*, *Tetragnatha maxillosa*, *Oxyopes matiensis*, *Pardosa birmanica*, *Pardosa patapatensis*, *Pardosa pullata*, while the predatory arthropods were *Libellula* sp., *Neurothemis fluctuans*, *Ortetrum sabina*, *Ortetrum testaceum*, *Mantis religiosa*, *Conocephalus longipennis*

Neutral insects of the Diptera order decreased in abundance in the plots applied with abamectin. Although they were neutral for plants, they were important in the agro-ecosystem for alternative prey to the generalist predators (spiders). According to Settle et al. (1996), neutral insects can maintain the existence of generalist predators when in the fields under a condition without herbivores. In this study, a decrease in abundance was found in the Diptera Order by abamectin. Therefore, abamectin in addition to reducing the abundance of spiders, predatory arthropods, reduced the abundance of neutral insects and showed that the abamectin was broad-spectrum (Ananiev et al. 2002).

The results of this study conclude that bioinsecticide *B. bassiana* of doses of 3 and 4 L.ha⁻¹ once in two weeks has an impact on reducing the number of non-target arthropods species (spiders, predatory arthropods, and parasitoids), but bioinsecticides *B. bassiana* has no impact to the abundance of spiders, predatory arthropods, and parasitoids. The ideal dosage to reduce the abundance of paddy insect pests (herbivores) is 2 L.ha⁻¹. For this reason, the right dose to suppress the abundance of paddy insect pests by not decreasing the abundance and diversity of non-target species is 2 L.ha⁻¹. Bioinsecticide spraying should be carried out when the abundance of insect pests is high, while the abundance of predators and parasitoids is still low in the fields so that spraying does not have an impact on decreasing the abundance and diversity of non-target arthropod species.

The impact of bioinsecticide overdoses of *Beauveria bassiana* on species diversity and abundance of not targeted arthropods in South Sumatra freshwater swamp paddy

Abstract. Bioinsecticides have been shown to reduce insect pest populations, but it is necessary to monitor the effect of bioinsecticide overdoses on non-target arthropods because they are abundant in rice fields. This study aimed to analyze the impact of bioinsecticide overdoses of *B. bassiana* on species diversity and abundance of non-target arthropods. Bioinsecticides derived from *Beauveria bassiana* were sprayed on the paddy every two weeks until the ripening stage, at a dose of 1, 2, 3, 4 L.ha⁻¹, control (without insecticide), and abamectin as prescribed. The abundance of spiders and predatory arthropods did not decrease when bioinsecticides were applied but the abundance of spiders, especially Lycosidae and Salticidae dropped significantly when abamectin was applied. The abundance of the parasitoid decreased significantly when abamectin was applied, but the abundance of parasitoids applied by bioinsecticide was not significantly different from those of control. The abundance of insect pests started to decrease when bioinsecticide was applied to 2, 3 or 4 L.ha⁻¹. The diversity species of non-target arthropods (spiders, predatory arthropods, and parasitoids) tended to decrease when it was applied bioinsecticides 3 and 4 L.ha⁻¹ or abamectin, but their abundance remained high and no species dominance was found. For this reason, the correct dosage for suppressing insect pests abundance by not decreasing the abundance and diversity of non-target species is 2 L.ha⁻¹ and applied when herbivore abundance is high.

Key words: abamectin, parasitoids, insect pests, predatory arthropods, spiders

Running title: *Beauveria* impact on not targeted arthropods

INTRODUCTION

Freshwater swamps are wetland ecosystems flooded with river water or rain throughout the year. The duration of the puddle in freshwater swamps depends on the typology of the land, namely deep, rather deep, and shallow. The swamp typology is generally inundated for most of the year (October to July), rather deep swamps are inundated from November to June, and shallow swamps are inundated from November to April. When lands are inundated, smallholders usually underutilize their lands. Herlinda et al. (2018) stated that the smallholders started to grow paddy in April or no later than July. They generally grew once a year (Herlinda et al. 2018; Lakitan et al. 2019). Therefore, the land productivity and cropping intensity were low (Lakitan et al. 2019).

Increasing land productivity needs to be conducted carefully and sustainably because freshwater swamps are fragile ecosystems (Lakitan et al. 2019; Siaga et al. 2019). The efforts of increasing land productivity were started by business farmers by regulating water management and damming/canalization of land covering an area of between 250 and 500 ha so that they can increase the intensity of rice planting from once a year to two or three times a year. However, according to Herlinda et al. (2019a) the increase of planting intensity caused business farmers to start applying intensive and scheduled synthetic insecticides. In order to maintain a sustainable agriculture, it is necessary to introduce business farmers and smallholders the bioinsecticide which is relatively environmentally friendly and safe for rice products.

Bioinsecticides made from entomopathogenic fungi, such as *Beauveria bassiana*, have been proven to be effective in controlling various species of insect pests. *B. bassiana* can kill paddy insects such as brown plant hoppers (BPH) (Li et al. 2014; Sumikarsih et al. 2019), *Spodoptera litura* (Ayudya et al. 2019). The research results in the laboratory proved that *B. bassiana* did not harm the natural enemies of BPH (non-target arthropods) (Firouzbakht et al. 2015; Gholamzadeh-Chitgar et al. 2017). However, caution is needed in applying the bioinsecticide because the non-target arthropod species is very abundant, rich, and diverse in the paddy ecosystem of freshwater swamps in South Sumatra, such as spiders (Herlinda et al. 2018), predatory insects, parasitoids, and neutral insects (Herlinda et al. 2019b; Karenina et al. 2019) if an overdose can affect the abundance and diversity of non-target arthropods. **The neutral insects, which were insects that did not act as herbivores or natural enemies of herbivores.** This study aimed to analyze the impact of bioinsecticide overdoses of *B. bassiana* on species diversity and abundance of non-target arthropods.

MATERIALS AND METHODS

This research has been carried out in the village of Pelabuhan Dalam, Pemulutan Subdistrict, Ogan Ilir District, South Sumatra, which is a center of freshwater swampy rice. The research site is surrounded by a paddy monoculture of ± 800 ha, which is generally planted from April or May to September or November each year. The field experiment was carried out from April to September 2018, and then the arthropods samples were taken and identified in the laboratory from October 2018 to March 2019. Paddy cultivation methods followed the pattern carried out by the smallholders but this

study used certified Mekongga varieties with purple label and planting system of "Jajar legowo" 2:1 with a spacing of 50x25x12.5 cm³. The area of each treatment plot was 38x20 m² which was repeated 3 times (total 2280 m²) where the distance between plots was 10 m.

Preparation of land and paddy seedlings

Preparation of land and rice planting began with tillage, seeding, planting and maintaining of paddy. Land management was conducted using mini plows and mashed using hoes. After the soil was processed, manure with a dose of 1 ton.ha⁻¹ was mixed into the treated soil. The paddy seeds were first soaked with water for 24 h, and then the seeds were planted using a "samir" system. The varieties used were certified with purple labels and a dose of 50 kg.ha⁻¹. After the seedlings were 5 days old, the seeds were moved into shallow rice fields and waited until they reached 14 days old. Then, the 14-day-old seedlings were transplanted in the fields.

Paddy planting and maintenance

The paddy planted with a 2:1 "jajar legowo" system with the plant spacing of 50x25x12.5 cm³. The number of seedlings planted is 2-3 stems per hole. The maintenance was carried out by mechanical weeding using sickles. The water management used pumping. The fertilization used liquid compost extract at a dose of 1 L.ha⁻¹ per two weeks from the age of 2 weeks to milky stage. The making of liquid compost extraction used the method of Suwandi et al. (2012) was carried out by means of 2 L of microbial culture of remodel mixed with 200 L of water, 10 kg of manure, 2 kg of NPK fertilizer, and 2 kg of phosphate fertilizer and fermented for 1-2 weeks. The liquid compost extract containing *Trichoderma virens* was used for plant nutrition.

The producing of bioinsecticides and their applications

Bioinsecticides applied in this study were made from conidia of *B. bassiana* with a carrier material of compost shrimp shell and the making of the compost extract used the method of Suwandi et al. (2012). As a bioinsecticide stabilizer, 30% sucrose (w/v) volume of bioinsecticide and 1% (v/v) vegetable oil were added. Conidia *B. bassiana* was propagated in SDA media using the method of Safitri et al. (2018). After that, it was cultured in liquid media (SDB) incubated and shaken on a shaker for 7 days. This liquid culture was added to liquid compost extract as a carrier and stabilizer of sucrose and vegetable oil. This bioinsecticide was first stored for 1 month before being applied in paddy and the bioinsecticide conidia density was at least 1 x 10⁹ conidia.mL⁻¹.

Bioinsecticide was applied in the afternoon around 5 p.m. to prevent the death of conidia due to the ultraviolet light during the day. The doses used were 1, 2, 3, 4 L.ha⁻¹, control (without treatment=0 L.ha⁻¹), a commercial insecticide (abamectin). The spraying began when the paddy reached 14, 28, 42, 56, 70, 84 days old after the transplanting (DAT). Abamectin is a biological insecticide with broad-spectrum activity (Ananiev et al. 2002) and this product was chosen in this research due to farmers in Indonesia often using it to control a brown planthopper (BPH), *Nilaparvata lugens*.

Sampling arthropods in paddy

The sampling of arthropods in paddy was carried out using insect nets (sweep nets) using the method of Weilhoefer et al. (2017). The arthropods sampling was conducted 1x24 h after spraying the bioinsecticide in the morning around 6.00-7.00 am. The sampling was carried out in the morning when the arthropods were not very active so that the data obtained were more valid. The arthropods were taken as many as 5 nets whose scattered positions were taken in the plot and repeated three times. The study design used a randomized group design. The arthropod sampling was carried out when the paddy reached 15, 29, 43, 57, 71, 85 DAT. The arthropods samples were then taken to the laboratory for sorting, cleaning, and then put in vial bottles containing 70% alcohol. The arthropods were identified by referring to the source textbooks of Kalshoven (1981), McAlpine et al. (1987), and Barrion and Litsinger (1995)

Data analysis

The data on the number of individuals of each arthropod species from each treatment were used to analyze species abundance and diversity. The abundance of arthropods during one paddy planting season was compared between the treatments using ANOVA assisted by the Software Program of SAS University Edition 2.7 9.4 M5. The species diversity was analyzed using the Shannon-Wiener (H') index, dominance (D), and Evenness (E) using the Magurran handbook (Magurran 1988). The grouping data were based on guilds, namely predators (spiders and predatory insects), parasitoids, herbivores, and neutral insects displayed in graphical forms. The non-target guilds were focused on predators (spiders and predatory insects) and parasitoids.

RESULTS AND DISCUSSION

The arthropods species in paddy applied with bioinsecticide

Predatory species found in this study were grouped into spiders and predatory insects. During one paddy planting season, all spider species were found as many as 31 species (Table 1). The dominant spider species found include *Pardosa*

birmanica, *Pardosa patapatensis*, *Pardosa pseudoannulata*, *Pardosa pullata*, *Pardosa sumatrana*. The number of species found in each bioinsecticide dose showed a tendency, the higher the dose the less number of species found in the paddy. The number of spider species dropped dramatically in plots at 4 L.ha⁻¹ and abamectin. In addition to spiders, predatory insects were found during one paddy planting season as many as 20 species (Table 2). The dominant predatory insects which were found were *Micrapis inops*, *Verania lineata*, *Ophionea nigrofasciata*, and *Paederus fuscipes*. The number of species found decreases with the increasing doses of bioinsecticide and the application of abamectin. The number of spider species dropped dramatically in plots at 3 and 4 L.ha⁻¹ and abamectin.

All parasitoids species found were 12 species (Table 3). The dominant parasitoids species were found, among others *Gonatocerus ashmeadi*, *Netomocera minuta*, *Snellenius manilae*, *Xanthopimpla punctata*. The number of species found showed a decrease in bioinsecticide plots at a dose of 4 L.ha⁻¹ and abamectin. The lowest number of parasitoid species was found in the abamectin plot, which was only 3 species (*Helorus anomalipes*, *Pteromalus* sp., and *Stictopisthus* sp.), however the abundance were not significantly different compared to the other plots.

There were 22 species of herbivores found throughout the paddies. (Table 4). The dominant herbivores species were found, among others *Leptocorisa acuta*, *Nephotetix viresces*, *Spodoptera litura*, *Nilaparvata lugens*, *Pelopidas mathias*. The number of herbivores species found in plots applied with bioinsecticide doses of 3 and 4 L.ha⁻¹ and abamectin was lower than those applied with bioinsecticide doses of 1 and 2 L.ha⁻¹, and control (without insecticide). There were 5 species of neutral insects and the dominant ones were *Chironomus plumosus*, *Tipula maxima* (Table 5). The number of species found in each treatment showed an almost equal number of 4-5 species. Figure 1 showed some arthropods found in this study.

Abundance of arthropods in paddy applied with bioinsecticide

The total data of the abundance of predators consisting of spiders and predatory insects showed that the spider abundance significantly decrease in total abundance of all species on plots applied with abamectin; yet, on plots applied with bioinsecticide doses of 1-4 L.ha⁻¹ and control without insecticide there was no significant decrease in total spider abundance (Table 1). A decrease in total abundance in one family was due to the application of abamectin found in Lycosidae and Salticidae. The abundance of predatory insects did not decrease in the plots applied with bioinsecticide, abamectin, and control (Table 2).

The parasitoid abundance of Hymenoptera order decreased significantly when abamectin was applied but the parasitoid abundance applied with bioinsecticide was not significantly different from that of the control (Table 3). The lowest abundance of parasitoids was found in the plot which was applied with abamectin, only one was found during one paddy planting season.

The abundance of herbivores in plots applied with bioinsecticide and abamectin decreased significantly when compared to those of the controls (Table 4). From the bioinsecticide field, there were found *Pelopidas mathias* larvae parasitized by *B. bassiana* (Figure 2). The families that had abundance decreased significantly were Noctuidae (*Spodoptera litura*) and Acrididae. The abundance of *Spodoptera litura* decreased when the bioinsecticide dose was applied 2 L.ha⁻¹ and it was not significantly different from the dose of 3 and L.ha⁻¹. Therefore, the dosage of bioinsecticide 2 L.ha⁻¹ was able to reduce the abundance of *S. litura*.

The neutral insects did not experience a decrease in total abundance in the bioinsecticide, abamectin, and control plots, but the Diptera order decreased its abundance in the plots applied with bioinsecticide and abamectin (Table 5). There were 5 species of neutral insects found in this study generally acting as pollinators, organic matter-decomposer, and an alternative prey for spiders.

Based on the comparison of abundance among the guilds (predators, parasitoids, herbivores, and neutral insects) the abundance of all guilds in plots applied with abamectin tended to be lower compared to control plots and bioinsecticides (Figure 3). The abundance of neutral insects and parasitoids from the beginning of planting to before harvest is always lower than other guilds. The most ideal abundance of predators was shown to be much higher than the that of herbivores (predator's main prey) on control plots and plots applied with doses of 1 and 2 bioinsecticides, whereas in plots doses of 3 and 4 L.ha⁻¹ and abamectin abundance of predators drastically decreased in herbivores abundance as well. Thus, the bioinsecticide in doses of 3 and 4 L.ha⁻¹ and abamectin in addition to reducing the abundance of herbivores reduced the abundance of arthropods that were not targeted (predator).

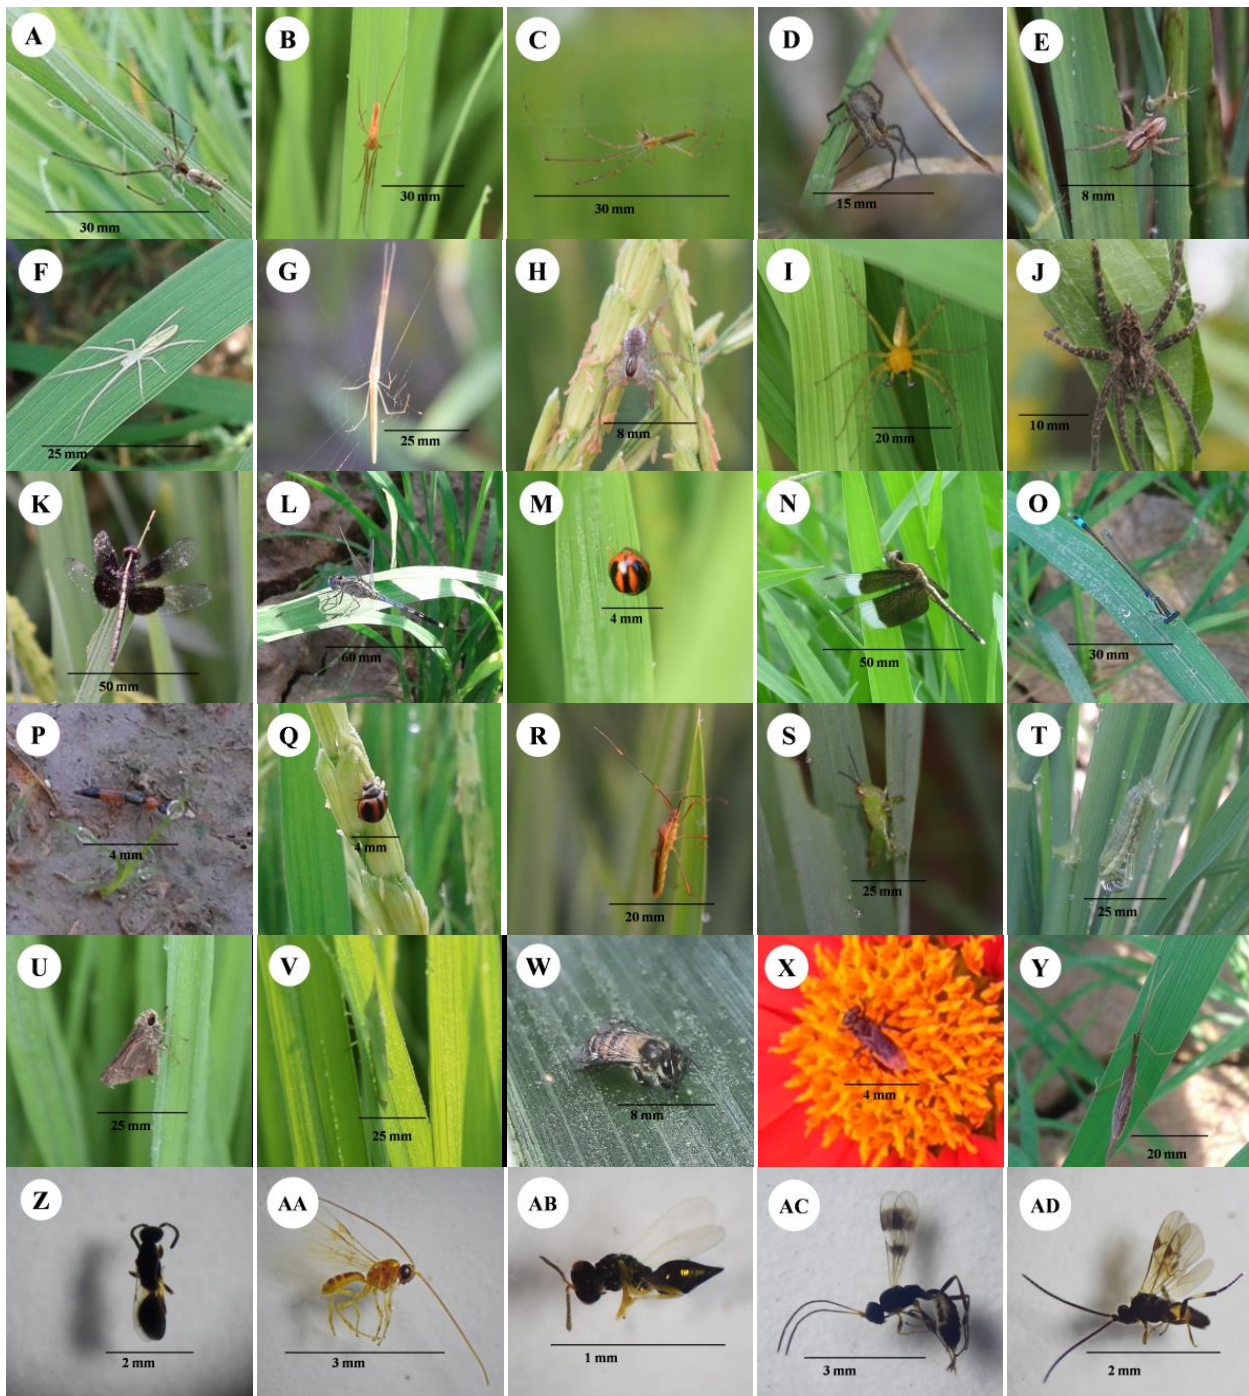

Figure 1. Arthropods found on paddy field of this research: *Tetragnatha virescens* (A), *Tetragnatha vermivormis* (B), *Tetragnatha ilavaca* (C), *Pardosa pseudoannulata* (D), *Pardosa sumatrana* (E), *Tetragnatha maxillosa* (F), *Tetragnatha javana* (G), *Pardosa birmanica* (H), *Oxyopes javanus* (I), *Pardosa pulata* (J), *Libellula* sp. (K), *Orthetrum sabina* (L), *Micraspis inops* (M), *Libellula luctuosa* (N), *Ischnura senegalensis* (O), *Paederus fuscipes* (P), *Verania lineata* (Q), *Leptocoris acuta* (R), *Valanga nigricornis* (S), *Spodoptera litura* (T), *Pelopidas mathias* (U), *Acrida turrata* (V), Apidae (W), *Trigona* sp. (X), *Tipula maxima* (Y), *Hemiptarsenus anementus* (Z), *Xanthopimpla punctata* (AA), *Pteromalus* sp. (AB), *Stictopisthus* sp. (AC), *Snellenius manila* (AD).

Characteristics of the arthropods community in paddy with bioinsecticide application

The species diversity (on average) was higher for spiders found in control plots applied with bioinsecticide in doses of 1 and 2 L.ha⁻¹ compared to bioinsecticide plots of 3 and 4 L.ha⁻¹ and abamectin (Table 6); still, the domination of spider species was not found in all plots. The decreased diversity of species predatory insects began to occur in plots applied with bioinsecticide in doses of 2, 3, and 4 L.ha⁻¹ and abamectin (Table 7). The lowest diversity of predatory insect species was found in the abamectin plot.

Parasitoid species diversity (on average) decreased in plots applied with bioinsecticide doses of 2, 3 and 4 L.ha⁻¹ and abamectin (Table 8). In all plots there were no species domination found. On the contrary, the diversity of herbivores species (on average) was higher in the plots applied with bioinsecticide doses of 3 and 4 L.ha⁻¹. However, in all of these

plots there was no domination of herbivores species (Table 9). The decrease in diversity of species neutral insects was found in the plots applied with bioinsecticides in doses of 2, 3, 4 L.ha⁻¹ and abamectin; yet, no species dominance was found (Table 10). In addition, the abundance of neutral insects in all plots was lower than the abundance of other guilds.

Discussion

The abundance of spiders and predatory arthropods did not decrease when bioinsecticides derived from *B. bassiana* were applied. The spiders and predatory arthropods were more resistant to *B. bassiana* and proved that *B. bassiana* did not adversely affect the predator. Many studies suggest that *B. bassiana* is a specific fungus that only kills insects from certain orders, such as Lepidoptera (Safitri et al. 2018; Ayudya et al. 2019) or Homoptera (Sumikarsih et al. 2019), whereas predators found in this study were spiders and insects of the order Coleoptera and Odonata, not those of the Order Lepidoptera or Homoptera. Entomopathogenic fungi are generally harmless to spiders (Yuliani 2016) and Coleoptera (Ngin et al. 2017). So, the application of the *B. bassiana* supported the existence of the spiders and predatory arthropods so that they are able to suppress insect pest populations which ultimately can support agroecosystem stability. Gholamzadeh-Chitgar et al. (2017) added that the *B. bassiana* did not harm the predators of brown plant hoppers, for example a predatory bug (*Andrallus spinidens*) of the Hemiptera Order.

The abundance of spiders, especially Lycosidae and Salticidae, decreased significantly when applied with commercial insecticides from the active ingredient abamectin. The data were in line with the research results of Prabawati et al. (2019) who found that spider abundance dropped significantly when paddy was sprayed with abamectin. Abamectin is a broad spectrum insecticide that can kill many species of arthropods (Ananiev et al. 2002). In addition, the abundance of the Hymenoptera parasitoid also decreased significantly when abamectin was applied. Sasmito et al. (2017) reported that abamectin could reduce the ability of the brown planthopper parasitoid (*Anagrus nilaparvatae*) in parasitizing and also reduced the abundance of these parasitoid offspring.

The abundance of herbivores started to decrease when applied with bioinsecticides of 2, 3 or 4 L.ha⁻¹, but at doses of 3 or 4 L.ha⁻¹ the diversity of species of non-target arthropods (predators and parasitoids) began to decrease. Consequently, the ideal dose to reduce the abundance of herbivores which are insect pests of paddy is 2 L.ha⁻¹ and spraying is conducted when the abundance of predators and parasitoids is low. Herbivores decreased in abundance after bioinsecticides derived from *B. bassiana* were applied; and the herbivores found in this study included *N. lugens*, *P. mathias*, *Spodoptera litura*. Herbivores found to be attacked by *B. bassiana* in the field were *P. mathias* and *S. litura* and both belonged to the Lepidoptera Order.

The ill Lepidoptera larvae found in the bioinsecticide plot were shown to show characteristics that were attacked by *B. bassiana*. Caterpillars were found hanging on the tips of paddy leaves and their bodies were dry, hard, and stiff. The ventral abdomen was covered with white mycelia. This sick caterpillar did not smell. The fungus from the sick caterpillar after being isolated and grown on PDA media resulted in a white colony and conidia growing in a round shape and hyaline color. The fungal morphological features found were in accordance with the results of identification of *B. bassiana* by Humber (2005) stating that mycelia of *B. bassiana* arises from the exoskeleton of insects and covers all parts of the integument surface so that the insect bodies are visibly white, reverse pale to yellow colony, hyaline or colorless, 1-celled, and globular and conidia, and insulated hypha. The characteristics of *P. mathias* larvae attacked by *B. bassiana* were the same as those of insects (*N. lugens*) attacked by *B. bassiana* which, according to Sumikarsih et al. (2019), the body is dry, hard, stiff, and odorless and from the insect's body appears a white mycelia.

Although the data of the abundance of non-target arthropods (spiders, predatory arthropods, and parasitoids) did not decrease when overused bioinsecticide was applied, their species diversity tended to decrease when applied with bioinsecticide doses of 3 and 4 L.ha⁻¹ or abamectin. This decrease resulted from the reduced number of species that survived in plots applied with bioinsecticide doses of 3 and 4 L.ha⁻¹ or abamectin. Therefore, this study does not recommend using doses of 3 or 4 L per 2 weeks because the non-target species that have immature stages (eggs, larvae, and pupae) in the soil can reduce their species. The highest decrease in the number of species was found in the plot applied with abamectin. Some species of non-target arthropods got sensitive to abamectin applications, namely species of web-building spiders and Carabidae (Prabawati et al. 2019), parasitoids (*Anagrus nilaparvatae*) (Sasmito et al. 2017). In this study the spider species sensitive to high doses of bioinsecticides (3 and 4 L.ha⁻¹) were *Camaricus formosus*, *Oxyopes matiensis*, while the predatory arthropods included *Ischnura senegalensis*, *Libellula luctuosa*, *Ortetrum Sabina*. The spider species sensitive to abamectin were The spider species sensitive to abamectin were *Camaricus formosus*, *Tetragnatha maxillosa*, *Oxyopes matiensis*, *Pardosa birmanica*, *Pardosa patapatensis*, *Pardosa pullata*, while the predatory arthropods were *Libellula* sp., *Neurothemis fluctuans*, *Ortetrum sabina*, *Ortetrum testaceum*, *Mantis religiosa*, *Conocephalus longipenis*

Neutral insects of the Diptera order decreased in abundance in the plots applied with abamectin. Although they were neutral for plants, they were important in the agro-ecosystem for alternative prey to the generalist predators (spiders). According to Settle et al. (1996), neutral insects can maintain the existence of generalist predators when in the fields under a condition without herbivores. In this study, a decrease in abundance was found in the Diptera Order by abamectin. Therefore, abamectin in addition to reducing the abundance of spiders, predatory arthropods, reduced the abundance of neutral insects and showed that the abamectin was broad-spectrum (Ananiev et al. 2002).

The results of this study conclude that bioinsecticide *B. bassiana* of doses of 3 and 4 L.ha⁻¹ once in two weeks has an impact on reducing the number of non-target arthropods species (spiders, predatory arthropods, and parasitoids), but bioinsecticides *B. bassiana* has no impact to the abundance of spiders, predatory arthropods, and parasitoids. The ideal dosage to reduce the abundance of paddy insect pests (herbivores) is 2 L.ha⁻¹. For this reason, the right dose to suppress the abundance of paddy insect pests by not decreasing the abundance and diversity of non-target species is 2 L.ha⁻¹. Bioinsecticide spraying should be carried out when the abundance of insect pests is high, while the abundance of predators and parasitoids is still low in the fields so that spraying does not have an impact on decreasing the abundance and diversity of non-target arthropod species.

Abstract. Hanif KI, Herlinda S, Irsan C, Pujiastuti Y, Prabawati G, Hasbi, Karenina T. 2020. The impact of bioinsecticide overdoses of *Beauveria bassiana* on species diversity and abundance of not targeted arthropods in South Sumatra (Indonesia) freshwater swamp paddy. *Biodiversitas* 21: xxx. Bioinsecticides have been shown to reduce insect pest populations, but it is necessary to monitor the effect of bioinsecticide overdoses on non-target arthropods because they are abundant in rice fields. This study aimed to analyze the impact of bioinsecticide overdoses of *B. bassiana* on species diversity and abundance of non-target arthropods. Bioinsecticides derived from *Beauveria bassiana* were sprayed on the paddy every two weeks until the ripening stage, at a dose of 1, 2, 3, 4 L.ha⁻¹, control (without insecticide), and abamectin as prescribed. The abundance of spiders and predatory arthropods did not decrease when bioinsecticides were applied but the abundance of spiders, especially Lycosidae and Salticidae dropped significantly when abamectin was applied. The abundance of the parasitoid decreased significantly when abamectin was applied, but the abundance of parasitoids applied by bioinsecticide was not significantly different from those of control. The abundance of insect pests started to decrease when bioinsecticide was applied to 2, 3 or 4 L.ha⁻¹. The diversity species of non-target arthropods (spiders, predatory arthropods, and parasitoids) tended to decrease when it was applied bioinsecticides 3 and 4 L.ha⁻¹ or abamectin, but their abundance remained high and no species dominance was found. For this reason, the correct dosage for suppressing insect pests abundance by not decreasing the abundance and diversity of non-target species is 2 L.ha⁻¹ and applied when herbivore abundance is high.

Keywords: abamectin, parasitoids, insect pests, predatory arthropods, spiders

INTRODUCTION

Freshwater swamps are wetland ecosystems flooded with river water or rain throughout the year. The duration of the puddle in freshwater swamps depends on the typology of the land, namely deep, rather deep, and shallow. The swamp typology is generally inundated for most of the year (October to July), rather deep swamps are inundated from November to June, and shallow swamps are inundated from November to April. When lands are inundated, smallholders usually underutilize their lands. Herlinda et al. (2018) stated that the smallholders started to grow paddy in April or no later than July. They generally grew once a year (Herlinda et al. 2018; Lakitan et al. 2019). Therefore, the land productivity and cropping intensity were low (Lakitan et al. 2019).

Increasing land productivity needs to be conducted carefully and sustainably because freshwater swamps are fragile ecosystems (Lakitan et al. 2019; Siaga et al. 2019). The efforts of increasing land productivity were started by business farmers by regulating water management and damming/canalization of land covering an area of between 250 and 500 ha so that they can increase the intensity of rice planting from once a year to two or three times a year. However, according to Herlinda et al. (2019a) the increase of planting intensity caused business farmers to start

applying intensive and scheduled synthetic insecticides. In order to maintain a sustainable agriculture, it is necessary to introduce business farmers and smallholders the bioinsecticide which is relatively environmentally friendly and safe for rice products.

Bioinsecticides made from entomopathogenic fungi, such as *Beauveria bassiana*, have been proven to be effective in controlling various species of insect pests. *B. bassiana* can kill paddy insects such as brown plant hoppers (BPH) (Li et al. 2014; Sumikarsih et al. 2019), *Spodoptera litura* (Ayudya et al. 2019). The research results in the laboratory proved that *B. bassiana* did not harm the natural enemies of BPH (non-target arthropods) (Firouzbakht et al. 2015; Gholamzadeh-Chitgar et al. 2017). However, caution is needed in applying the bioinsecticide because the non-target arthropod species is very abundant, rich, and diverse in the paddy ecosystem of freshwater swamps in South Sumatra, such as spiders (Herlinda et al. 2018), predatory insects, parasitoids, and neutral insects (Herlinda et al. 2019b; Karenina et al. 2019) if an overdose can affect the abundance and diversity of non-target arthropods. The neutral insects, which were insects that did not act as herbivores or natural enemies of herbivores. This study aimed to analyze the impact of bioinsecticide overdoses of *B. bassiana* on species diversity and abundance of non-target arthropods.

MATERIALS AND METHODS

This research has been carried out in the village of Pelabuhan Dalam, Pemulutan Subdistrict, Ogan Ilir District, South Sumatra, which is a center of freshwater swampy rice. The research site is surrounded by a paddy monoculture of \pm 800 ha, which is generally planted from April or May to September or November each year. The field experiment was carried out from April to September 2018, and then the arthropods samples were taken and identified in the laboratory from October 2018 to March 2019. Paddy cultivation methods followed the pattern carried out by the smallholders but this study used certified Mekongga varieties with purple label and planting system of "Jajar legowo" 2:1 with a spacing of 50x25x12.5 cm³. The area of each treatment plot was 38x20 m² which was repeated 3 times (total 2280 m²) where the distance between plots was 10 m.

Preparation of land and paddy seedlings

Preparation of land and rice planting began with tillage, seeding, planting and maintaining of paddy. Land management was conducted using mini plows and mashed using hoes. After the soil was processed, manure with a dose of 1 ton.ha⁻¹ was mixed into the treated soil. The paddy seeds were first soaked with water for 24 h, and then the seeds were planted using a "samir" system. The varieties used were certified with purple labels and a dose of 50 kg.ha⁻¹. After the seedlings were 5 days old, the seeds were moved into shallow rice fields and waited until they reached 14 days old. Then, the 14-day-old seedlings were transplanted in the fields.

Paddy planting and maintenance

The paddy planted with a 2:1 "jajar legowo" system with the plant spacing of 50x25x12.5 cm³. The number of seedlings planted is 2-3 stems per hole. The maintenance was carried out by mechanical weeding using sickles. The water management used pumping. The fertilization used liquid compost extract at a dose of 1 L.ha⁻¹ per two weeks from the age of 2 weeks to milky stage. The making of liquid compost extraction used the method of Suwandi et al. (2012) was carried out by means of 2 L of microbial culture of remodel mixed with 200 L of water, 10 kg of manure, 2 kg of NPK fertilizer, and 2 kg of phosphate fertilizer and fermented for 1-2 weeks. The liquid compost extract containing *Trichoderma virens* was used for plant nutrition.

The producing of bioinsecticides and their applications

Bioinsecticides applied in this study were made from conidia of *B. bassiana* with a carrier material of compost shrimp shell and the making of the compost extract used the method of Suwandi et al. (2012). As a bioinsecticide stabilizer, 30% sucrose (w/v) volume of bioinsecticide and 1% (v/v) vegetable oil were added. Conidia *B. bassiana* was propagated in SDA media using the method of Safitri et al. (2018). After that, it was cultured in liquid media (SDB) incubated and shaken on a shaker for 7 days. This liquid culture was added to liquid compost extract as a

carrier and stabilizer of sucrose and vegetable oil. This bioinsecticide was first stored for 1 month before being applied in paddy and the bioinsecticide conidia density was at least 1×10^9 conidia.mL⁻¹.

Bioinsecticide was applied in the afternoon around 5 p.m. to prevent the death of conidia due to the ultraviolet light during the day. The doses used were 1, 2, 3, 4 L.ha⁻¹, control (without treatment=0 L.ha⁻¹), a commercial insecticide (abamectin). The spraying began when the paddy reached 14, 28, 42, 56, 70, 84 days old after the transplanting (DAT). Abamectin is a biological insecticide with broad-spectrum activity (Ananiev et al. 2002) and this product was chosen in this research due to farmers in Indonesia often using it to control a brown planthopper (BPH), *Nilaparvata lugens*.

Sampling arthropods in paddy

The sampling of arthropods in paddy was carried out using insect nets (sweep nets) using the method of Weillhoefer et al. (2017). The arthropods sampling was conducted 1x24 h after spraying the bioinsecticide in the morning around 6.00-7.00 am. The sampling was carried out in the morning when the arthropods were not very active so that the data obtained were more valid. The arthropods were taken as many as 5 nets whose scattered positions were taken in the plot and repeated three times. The study design used a randomized group design. The arthropod sampling was carried out when the paddy reached 15, 29, 43, 57, 71, 85 DAT. The arthropods samples were then taken to the laboratory for sorting, cleaning, and then put in vial bottles containing 70% alcohol. The arthropods were identified by referring to the source textbooks of Kalshoven (1981), McAlpine et al. (1987), and Barrion and Litsinger (1995)

Data analysis

The data on the number of individuals of each arthropod species from each treatment were used to analyze species abundance and diversity. The abundance of arthropods during one paddy planting season was compared between the treatments using ANOVA assisted by the Software Program of SAS University Edition 2.7 9.4 M5. The species diversity was analyzed using the Shannon-Wiener (H') index, dominance (D), and Evenness (E) using the Magurran handbook (Magurran 1988). The grouping data were based on guilds, namely predators (spiders and predatory insects), parasitoids, herbivores, and neutral insects displayed in graphical forms. The non-target guilds were focused on predators (spiders and predatory insects) and parasitoids.

RESULTS AND DISCUSSION

The arthropods species in paddy applied with bioinsecticide

Predatory species found in this study were grouped into spiders and predatory insects. During one paddy planting season, all spider species were found as many as 31 species (Table 1). The dominant spider species found include

Pardosa birmanica, *Pardosa patapatensis*, *Pardosa pseudoannulata*, *Pardosa pullata*, *Pardosa sumatrana*. The number of species found in each bioinsecticide dose showed a tendency, the higher the dose the less number of species found in the paddy. The number of spider species dropped dramatically in plots at 4 L.ha⁻¹ and abamectin. In addition to spiders, predatory insects were found during one paddy planting season as many as 20 species (Table 2).

The dominant predatory insects which were found were *Micrapis inops*, *Verania lineata*, *Ophionea nigrofasciata*, and *Paederus fuscipes*. The number of species found decreases with the increasing doses of bioinsecticide and the application of abamectin. The number of spider species dropped dramatically in plots at 3 and 4 L.ha⁻¹ and abamectin.

Table 1. Spider abundance inhabiting on the paddy applied with bioinsecticide of *Beauveria bassiana*, control without treatment (0 L.ha⁻¹), and abamectin

Total of abundance (N)	11.83 ^b	11.00 ^b	10.67 ^b	10.17 ^b	9.83 ^b	5.17 ^a	11.68	0.00	0.45
Total of species (S)	17	24	21	18	16	13			

Note: * = significantly different; values within a row followed by the same letters were not significantly different at P<0.05 according to Tukey's HSD test.

All parasitoids species found were 12 species (Table 3). The dominant parasitoids species were found, among others *Gonatocerus ashmeadi*, *Netomocera minuta*, *Snellenius manilae*, *Xanthopimpla punctata*. The

number of species found showed a decrease in bioinsecticide plots at a dose of 4 L.ha⁻¹ and abamectin. The lowest number of parasitoid species was found in the abamectin plot, which was only 3 species (*Helorus*

anomalipes, *Pteromalus* sp., and *Stictopisthus* sp.), however the abundance were not significantly different compared to the other plots.

There were 22 species of herbivores found throughout the paddies. (Table 4). The dominant herbivores species were found, among others *Leptocorisa acuta*, *Nephotetix virens*, *Spodoptera litura*, *Nilaparvata lugens*, *Pelopidas mathias*. The number of herbivores species found in plots

applied with bioinsecticide doses of 3 and 4 L.ha⁻¹ and abamectin was lower than those applied with bioinsecticide doses of 1 and 2 L.ha⁻¹, and control (without insecticide). There were 5 species of neutral insects and the dominant ones were *Chironomus plumosus*, *Tipula maxima* (Table 5). The number of species found in each treatment showed an almost equal number of 4-5 species. Figure 1 showed some arthropods found in this study.

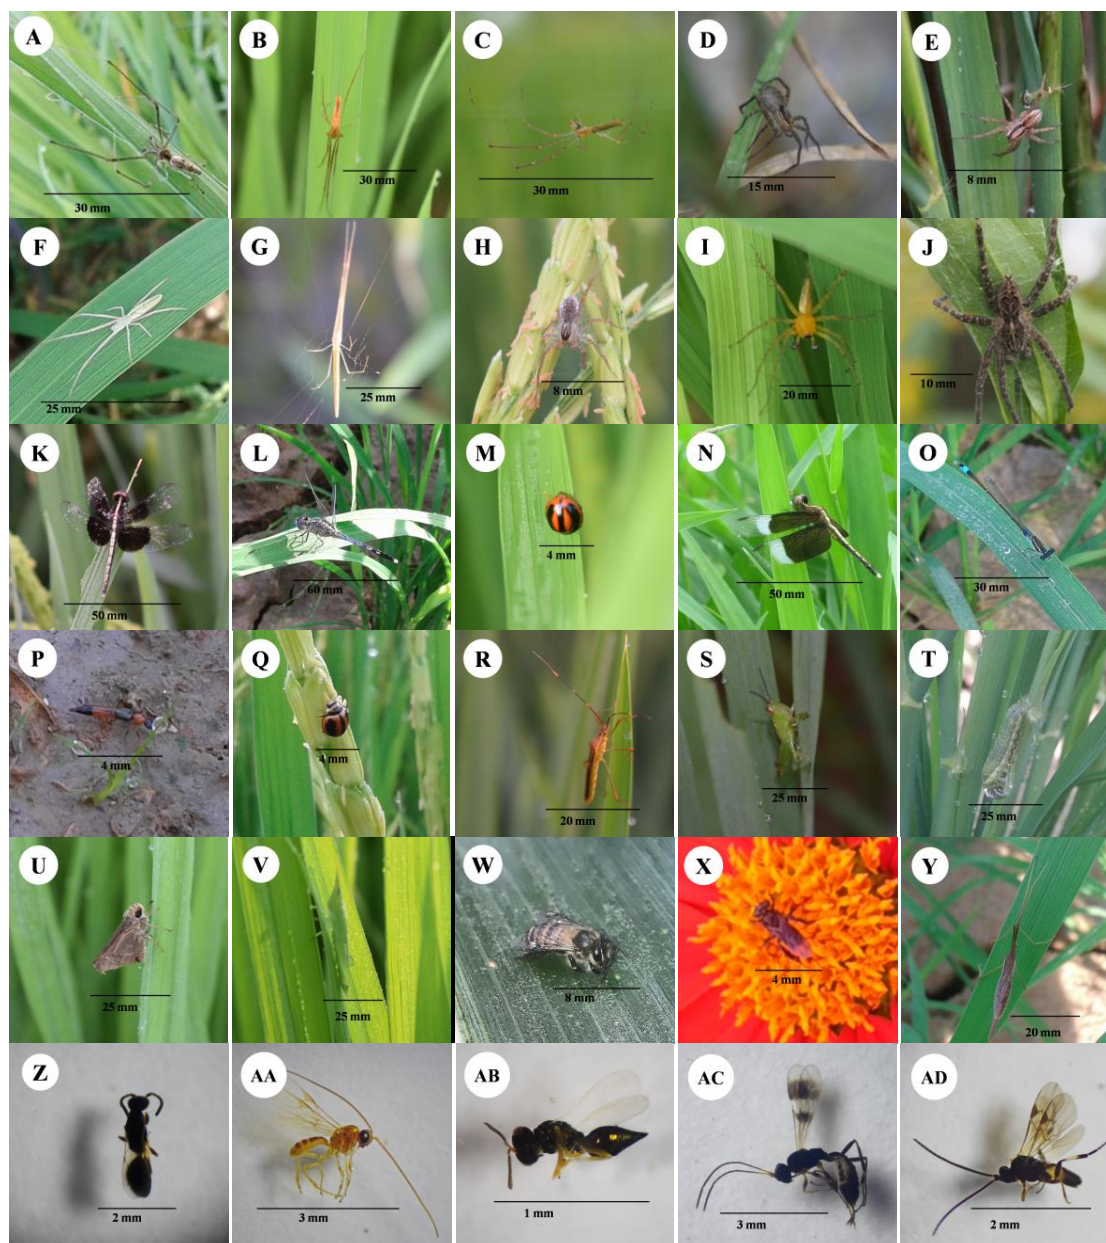

Figure 1. Arthropods found on paddy field of this research: *Tetragnatha virescens* (A), *Tetragnatha vermivormis* (B), *Tetragnatha ilavaca* (C), *Pardosa pseudoannulata* (D), *Pardosa sumatrana* (E), *Tetragnatha maxillosa* (F), *Tetragnatha javana* (G), *Pardosa birmanica* (H), *Oxyopes javanus* (I), *Pardosa pulata* (J), *Libellula* sp. (K), *Orthetrum sabina* (L), *Micraspis inops* (M), *Libellula luctuosa* (N), *Ischnura senegalensis* (O), *Paederus fuscipes* (P), *Verania lineata* (Q), *Leptocorisa acuta* (R), *Valanga nigricornis* (S), *Spodoptera litura* (T), *Pelopidas mathias* (U), *Acrida turrata* (V), *Apidae* (W), *Trigona* sp. (X), *Tipula maxima* (Y), *Hemiptarsenus anementus* (Z), *Xanthopimpla punctata* (AA), *Pteromalus* sp. (AB), *Stictopisthus* sp. (AC), *Snellenius manila* (AD).

Abundance of arthropods in paddy applied with bioinsecticide

The total data of the abundance of predators consisting of spiders and predatory insects showed that the spider abundance significantly decrease in total abundance of all species on plots applied with abamectin; yet, on plots applied with bioinsecticide doses of 1-4 L.ha⁻¹ and control without insecticide there was no significant decrease in total spider abundance (Table 1). A decrease in total abundance in one family was due to the application of abamectin found in Lycosidae and Salticidae. The abundance of predatory insects did not decrease in the plots applied with bioinsecticide, abamectin, and control (Table 2).

The parasitoid abundance of Hymenoptera order decreased significantly when abamectin was applied but the parasitoid abundance applied with bioinsecticide was

not significantly different from that of the control (Table 3). The lowest abundance of parasitoids was found in the plot which was applied with abamectin, only one was found during one paddy planting season.

The abundance of herbivores in plots applied with bioinsecticide and abamectin decreased significantly when compared to those of the controls (Table 4). From the bioinsecticide field, there were found *Pelopidas mathias* larvae parasitized by *B. bassiana* (Figure 2). The families that had abundance decreased significantly were Noctuidae (*Spodoptera litura*) and Acrididae. The abundance of *Spodoptera litura* decreased when the bioinsecticide dose was applied 2 L.ha⁻¹ and it was not significantly different from the dose of 3 and L.ha⁻¹. Therefore, the dosage of bioinsecticide 2 L.ha⁻¹ was able to reduce the abundance of *S. litura*.

Figure 2. An insect pest, *Pelopidas mathias* infected by *B. bassiana* on paddy field

The neutral insects did not experience a decrease in total abundance in the bioinsecticide, abamectin, and control plots, but the Diptera order decreased its abundance in the plots applied with bioinsecticide and abamectin (Table 5). There were 5 species of neutral insects found in this study generally acting as pollinators, organic matter-decomposer, and an alternative prey for spiders.

Based on the comparison of abundance among the guilds (predators, parasitoids, herbivores, and neutral insects) the abundance of all guilds in plots applied with abamectin tended to be lower compared to control plots and bioinsecticides (Figure 3). The abundance of neutral insects and parasitoids from the beginning of planting to before harvest is always lower than other guilds. The most ideal abundance of predators was shown to be much higher than the that of herbivores (predator's main prey) on control plots and plots applied with doses of 1 and 2 bioinsecticides, whereas in plots doses of 3 and 4 L.ha-1 and abamectin abundance of predators drastically decreased in herbivores abundance as well. Thus, the bioinsecticide in doses of 3 and 4 L.ha-1 and abamectin in addition to reducing the abundance of herbivores reduced the abundance of arthropods that were not targeted (predator).

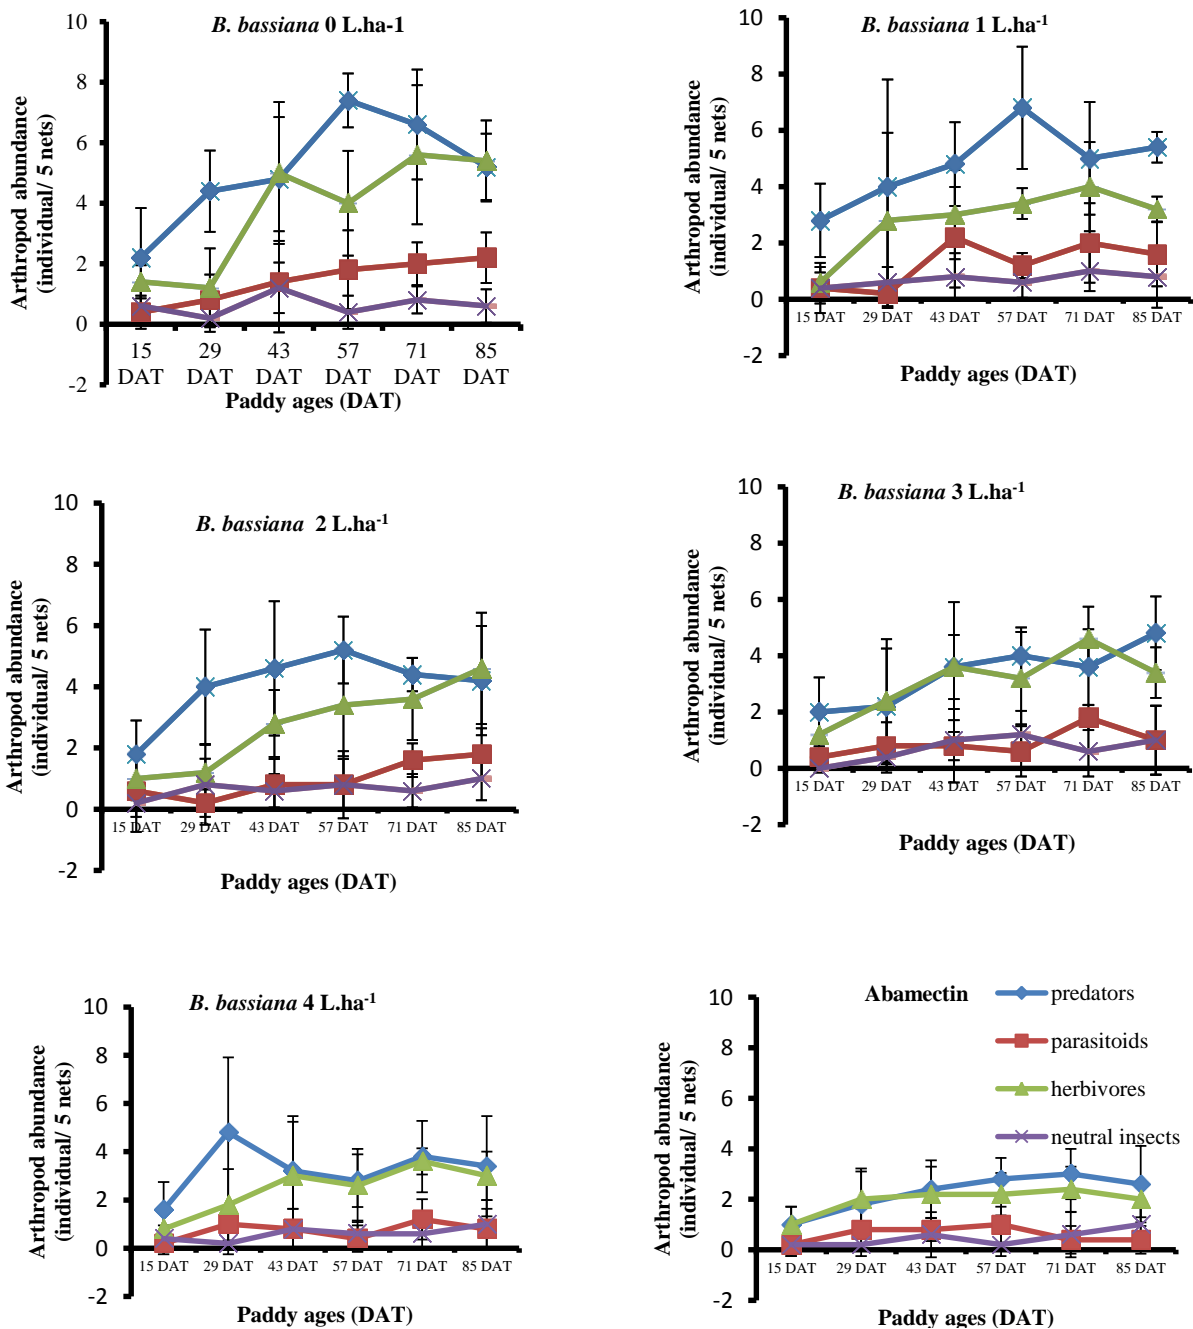

Figure 3. Arthropod abundance on the paddy applied with bioinsecticide of *Beauveria bassiana*, control without treatment (0 L.ha⁻¹), and abamectin, DAT = days after transplanting

Characteristics of the arthropods community in paddy with bioinsecticide application

The species diversity (on average) was higher for spiders found in control plots applied with bioinsecticide in doses of 1 and 2 L.ha⁻¹ compared to bioinsecticide plots of 3 and 4 L.ha⁻¹ and abamectin (Table 6); still, the domination of spider species was not found in all plots. The decreased diversity of species predatory insects began to occur in plots applied with bioinsecticide in doses of 2, 3, and 4 L.ha⁻¹ and abamectin (Table 7). The lowest diversity of predatory insect species was found in the abamectin plot.

Parasitoid species diversity (on average) decreased in plots applied with bioinsecticide doses of 2, 3 and 4 L.ha⁻¹ and abamectin (Table 8). In all plots there were no species domination found. On the contrary, the diversity of herbivores species (on average) was higher in the plots applied with bioinsecticide doses of 3 and 4 L.ha⁻¹. However, in all of these plots there was no domination of herbivores species (Table 9). The decrease in diversity of species neutral insects was found in the plots applied with bioinsecticides in doses of 2, 3, 4 L.ha⁻¹ and abamectin; yet, no species dominance was found (Table 10). In addition,

the abundance of neutral insects in all plots was lower than the abundance of other guilds.

Discussion

The abundance of spiders and predatory arthropods did not decrease when bioinsecticides derived from *B. bassiana* were applied. The spiders and predatory arthropods were more resistant to *B. bassiana* and proved that *B. bassiana* did not adversely affect the predator. Many studies suggest that *B. bassiana* is a specific fungus that only kills insects from certain orders, such as Lepidoptera (Safitri et al. 2018; Ayudya et al. 2019) or Homoptera (Sumikarsih et al. 2019), whereas predators found in this study were spiders and insects of the order Coleoptera and Odonata, not those of the Order Lepidoptera or Homoptera. Entomopathogenic fungi are generally harmless to spiders (Yuliani 2016) and Coleoptera (Ngin et al. 2017). So, the application of the *B. bassiana* supported the existence of the spiders and predatory arthropods so that they are able to suppress insect pest populations which ultimately can support agroecosystem stability. Gholamzadeh-Chitgar et al. (2017) added that the *B. bassiana* did not harm the predators of brown plant hoppers, for example a predatory bug (*Andrallus spinidens*) of the Hemiptera Order.

The abundance of spiders, especially Lycosidae and Salticidae, decreased significantly when applied with commercial insecticides from the active ingredient abamectin. The data were in line with the research results of Prabawati et al. (2019) who found that spider abundance dropped significantly when paddy was sprayed with abamectin. Abamectin is a broad spectrum insecticide that can kill many species of arthropods (Ananiev et al. 2002). In addition, the abundance of the Hymenoptera parasitoid also decreased significantly when abamectin was applied. Sasmito et al. (2017) reported that abamectin could reduce the ability of the brown planthopper parasitoid (*Anagrus nilaparvatae*) in parasitizing and also reduced the abundance of these parasitoid offspring.

The abundance of herbivores started to decrease when applied with bioinsecticides of 2, 3 or 4 L.ha⁻¹, but at doses of 3 or 4 L.ha⁻¹ the diversity of species of non-target arthropods (predators and parasitoids) began to decrease. Consequently, the ideal dose to reduce the abundance of herbivores which are insect pests of paddy is 2 L.ha⁻¹ and spraying is conducted when the abundance of predators and parasitoids is low. Herbivores decreased in abundance after bioinsecticides derived from *B. bassiana* were applied; and the herbivores found in this study included *N. lugens*, *P. mathias*, *Spodoptera litura*. Herbivores found to be attacked by *B. bassiana* in the field were *P. mathias* and *S. litura* and both belonged to the Lepidoptera Order.

The ill Lepidoptera larvae found in the bioinsecticide plot were shown to show characteristics that were attacked by *B. bassiana*. Caterpillars were found hanging on the tips of paddy leaves and their bodies were dry, hard, and stiff. The ventral abdomen was covered with white mycelia. This sick caterpillar did not smell. The fungus from the sick caterpillar after being isolated and grown on SDA media resulted in a white colony and conidia growing in a round shape and hyaline color. The fungal morphological features found were in accordance with the results of identification of *B. bassiana* by Humber (2005) stating that mycelia of *B. bassiana* arises from the exoskeleton of insects and covers all parts of the integument surface so that the insect bodies are visibly white, reverse pale to yellow colony, hyaline or colorless, 1-celled, and globular and conidia, and insulated hypha. The characteristics of *P. mathias* larvae attacked by *B. bassiana* were the same as those of insects (*N. lugens*) attacked by *B. bassiana* which, according to Sumikarsih et al. (2019), the body is dry, hard, stiff, and odorless and from the insect's body appears a white mycelia.

Although the data of the abundance of non-target arthropods (spiders, predatory arthropods, and parasitoids) did not decrease when overdosed bioinsecticide was applied, their species diversity tended to decrease when applied with bioinsecticide doses of 3 and 4 L.ha⁻¹ or abamectin. This decrease resulted from the reduced number of species that survived in plots applied with bioinsecticide doses of 3 and 4 L.ha⁻¹ or abamectin. Therefore, this study does not recommend using doses of 3 or 4 L per 2 weeks because the non-target species that have immature stages (eggs, larvae, and pupae) in the soil can reduce their species. The highest decrease in the number of species was found in the plot applied with abamectin. Some species of non-target arthropods got sensitive to abamectin applications, namely species of web-building spiders and Carabidae (Prabawati et al. 2019), parasitoids (*Anagrus nilaparvatae*) (Sasmito et al. 2017). In this study the spider species sensitive to high doses of bioinsecticides (3 and 4 L.ha⁻¹) were *Camaricus formosus*, *Oxyopes matiensis*, while the predatory arthropods included *Ischnura senegalensis*, *Libellula luctuosa*, *Ortetrum Sabina*. The spider species sensitive to abamectin were *Camaricus formosus*, *Tetragnatha maxillosa*, *Oxyopes matiensis*, *Pardosa birmanica*, *Pardosa patapatensis*, *Pardosa pullata*, while the predatory arthropods were *Libellula* sp., *Neurothemis fluctuans*, *Ortetrum sabina*, *Ortetrum testaceum*, *Mantis religiosa*, *Conocephalus longipenis*

Neutral insects of the Diptera order decreased in abundance in the plots applied with abamectin. Although they were neutral for plants, they were important in the agro-ecosystem for alternative prey to the generalist predators (spiders). According to Settle et al. (1996), neutral insects can maintain the existence of generalist predators when in the fields under a condition without herbivores. In this study, a decrease in abundance was found in the Diptera Order by abamectin. Therefore, abamectin in addition to reducing the abundance of spiders, predatory arthropods, reduced the abundance of neutral insects and showed that the abamectin was broad-spectrum (Ananiev et al. 2002).

The results of this study conclude that bioinsecticide *B. bassiana* of doses of 3 and 4 L.ha⁻¹ applied every two weeks has an impact on reducing the number of non-target arthropods species (spiders, predatory arthropods, and parasitoids), but bioinsecticides *B. bassiana* has no impact to the abundance of spiders, predatory arthropods, and parasitoids. The ideal dosage to reduce the abundance of paddy insect pests (herbivores) is 2 L.ha⁻¹. For this reason, the right dose to suppress the abundance of paddy insect pests by not decreasing the abundance and diversity of non-target species is 2 L.ha⁻¹. Bioinsecticide spraying should be carried out when the abundance of insect pests is high, while the abundance of predators and parasitoids is still low in the fields so that spraying does not have an impact on decreasing the abundance and diversity of non-target arthropod species.

ACKNOWLEDGEMENTS

Thank you to the sponsor of this research, the Master Thesis Research (Penelitian Tesis Magister) program, Directorate of Research and Community Service (DRPM), Directorate General of Research and Development, Kemenristekdikti, with contract number: 096/SP2H/LT/DRPM/IV/2019. This research was chaired by Siti Herlinda.
