Abstract. *Arthrospira* production technology in catfish waste media can be an alternative to reduce environmental pollution. However, some environmental factors such as nutrition, light and water content can influence characterization of *Arthrospira* at the genetic and physiologic level. *Arthrospira platensis* is one of the phycocyanin-producing cyanobacteria and can be cultured using catfish culture wastewater. Water quality especially pH and salinity can effect of growth rate and rendement of phycocyanin from *Arthrospira platensis*. This study aimed to identify the species and morphological forms of *Arthrospira* cultured using technical fertilizer and waste media, as well as to know the phylogenetic trees between species in this study and the GeneBank based on the 16S rRNA gene, and determine the optimum of pH and salinity required in the medium of catfish culture wastewater to phycocyanin maximum production of *Arthrospira*. The optimization of pH and salinity method used Completely Randomized Design (CRD) factorial with 2 factors consisting of the first factor with 3 treatments and the second factor with 4 treatments and 3 replications. The first factor was pH of culture medium i.e. pH 6.5 ± 0.2, pH 8.5 ± 0.2 and pH 10.5 ± 0.2. The second factor was salinity of culture medium, that were salinity 0 ppt, 10 ppt, 20 ppt and 30 ppt. Parameters observed in *Arthrospira* include density, growth rate, rendement of phycocyanin, and decreased of total nitrogen and phosphate content in culture media. The results showed that morphology *Arthrospira* cultured on technical fertilizer media (AF) had a longer and helix filament compared to *Arthrospira* cultured on waste media (AW) which showed several linear and shorter filaments. Both samples have a genetic distance of 0.068 (6.8%). Phylogenetic trees indicated that AF had a close relationship with *Arthrospira platensis* petH from Japan (bootstrap value 95%). While AW formed a separate sub cluster of AF isolates and *Arthrospira platensis* petH from Japan (bootstrap value of 85%). The best treatment in this study was P2S3 (pH 8.5 ± 0.2 with salinity 20 ppt), which produced 0.867 grams maximum density, growth rate of 22.026 %·day⁻¹ and 11.347 mg·g⁻¹ rendement of phycocyanin.

Key words: catfish culture wastewater, DNA barcode, pH, phycocyanin, phylogenetic analysis, salinity, *Spirulina*(*Arthrospira*), 16S rRNA

Abbreviations: AF = *Arthrospira platensis* cultured on technical fertilizer media; AW= *Arthrospira platensis* cultured on waste media

Running title: a short title with five words

INTRODUCTION

Arthrospira is a genus of cyanobacterial microalgae, commonly known under the taxonomically incorrect brand name 'Spirulina' (Papapanagiotou & Gkelis, 2019). The cyanobacterial genus *Arthrospira* Stizenberger ex Gomont 1892 contains at present 23 species, along with 12 infraspecific taxa (Guiry & Guiry, 2018). They have variety characteristic of molecular, morphology, and physiology that based on polyphasic approach. Various genotypes are adaptable to various specialized ecosystems. The combination of different methods should be based on molecular sequencing as the basic approach, to which must be added other criteria (morphological, ecological) if they are available and which are distinct and recognizable in cyanobacterial populations (Komarek, 2016). A polyphasic approach to include all the criteria obtained from morphological, biochemical, molecular studies, and phylogenetic to understand cyanobacterial classification as like as *Arthrospira* classification (Komárek, 2018).

Recent studies have shown that *Arthrospira* can be used for treating wastewater, including effluent from fish culture, because the biomass can metabolize the nutrients and remove the pollutant from aquaculture effluent efficiently (Zhang et al., 2020). Industrial and processing wastes and by-products for culturing *Spirulina* (*Arthrospira*) are also being considered as alternative culture media, as like as aquaculture waste water (Ragaza et al. 2020, Wijayanti et al. 2018, Widyanoro et al., 2018). Aquaculture could apply an integrated strategy of

simultaneously treating aquaculture effluent while producing the biomass to supplement fish diets. The nutrient composition in their biomass depends on their environmental factor for growing biomass. Their character could be different with the various media for growth.

Basically, *Arthrospira's* morphology is characterized by trichomes that circular regularly (helical). However, abnormal morphology can also occur in *Arthrospira* as a circular shape that is irregular even linear. In some cultivation conditions, linear filaments can spontaneously return to the helix. However, there are significant differences in morphology, ultrastructure, physiology, biochemistry, and genetic characteristics between the original filament and the linear filament but not the difference between the original and the returned filament. Linearization in *Arthrospira* is a variation on the genetic level that can be caused by several environmental factors such as nutrition, light and content of water media for growth (Wang and Zhao 2005). According to Liu et al., (2016), DNA barcoding has developed as a reliable technology for identifying species based on variations in the sequence of standard DNA regions. This method is used successfully in a variety of biological applications including finding cryptic species, detecting invasive species, and identifying plants. DNA barcoding is a simple short genome sequence amplified via PCR using appropriate primers (Adamowicz, 2015). DNA barcoding using the 16S rRNA gene has been widely used to determine bacterial DNA characterization. Therefore, identification of *Arthrospira* using the 16S rRNA gene needs to be done to get the characterization of *Arthrospira* that is cultured on technical fertilizer and waste media and determine the phylogenetic tree structure that has been recorded in GenBank.

Culture of *Arthrospira (Spirulina)* in *Clarias* pond farming wasted water could have specific characterization for optimal pH value and salinity. Their adaptation to grow in organic waste water make change in bioactive and important compound production. Their biomass has a nutritional value of 55-70% protein, 6-10% lipid, 20% carbohydrate, besides being rich in minerals, vitamins, and pigments (Borowitzka et al., 2016; Vernes et al., 2016). Some color pigments that can be produced such as phycocyanin (blue pigment), allophycocyanin (blue-green) and phycoerythrin (red pigment) (Sharma and Tiwari, 2011; Vernes et al., 2015). Phycocyanin is pigment in *Arthrospira* which has functions as an antioxidant (Pirenantyo and Limantara., 2008), a source of food coloring, cosmetics, pharmaceuticals and drugs (Tang et al., 2020; Tiwari & Tiwari, 2020), anti-inflammatory, anti-oxidative and anticancer (Liu et al., 2013). One of the factors that influence phycocyanin levels is biomass (Taufiqurrahmi et al., 2017). The pH and salinity of culture media can affect the biomass of *Arthrospira* (Ciferri, 1983; Marek et al., 1987; Planes et al., 2002). Ismaiel et al. (2016) showed that the diversity of the chemical composition of biomass is influenced by the pH of the growth media. Value of pH and environmental factors, especially salinity, influence the productivity of cell biomass, photosynthesis, shape, and flow of cellular metabolic activity that affect the dynamics of cell composition (Hu, 2004). The optimal pH value for growth of *Arthrospira* sp is 7-10.5 (Hariyati, 2008), and salinity from 15-30 ‰ (Thajuddin and Subramanian, 2005). The salinity and pH value of *Arthrospira* culture media have been known to affect the morphology of the filament.

The aims of this study is characterizing morphological forms and DNA barcode based on the 16S rRNA gene of *Arthrospira (Spirulina)* cultured in fertilizer and waste water effluent of *Clarias* pond farming media, and determining optimal pH value and salinity of culture media for growth and phycocyanin production, especially in *Clarias* pond farming waste water media and morphological changes of their filament.

MATERIALS AND METHODS

Arthrospira cultured in agar media

Bacto agar was weighed as much as 2 g dissolved in 100 ml of water. The water used was swamp water and catfish culture waste that has been filtered and sterilized using an autoclave. Sterilized swamp water was then added with 0.02 gram MgSO₄ fertilizer; CaCl₂ 0.004 gram; EDTA 0.008 gram; urea 0.03 gram; ZA 0.132 grams; 0.4 gram baking soda; AB solution 1 ml (A solution 20 grams / 100 ml B solution 20 grams/100 ml water) and TSP 0.05 grams were then homogeneous using magnetic stirrers. Next, wasted water was sterilized by an autoclave then cooled. Bactoagar was added to the technical fertilizer and waste solution to be homogenized using a magnetic stirrer and then boiled using a hot plate until all the ingredients dissolve and then autoclave again. The agar media was made with a pH of 7 and a salinity of 10 g.L⁻¹.

Arthrospira cultivated in liquid media was taken 100 µl using micropipette and spread to the surface of a petri dish containing bactoagar media by using a sterilized spreader rod. Petri dishes were wrapped in wrapping plastic and then given a lamp lighting (light intensity 2000-4000 lux) with a dark: light ratio = 0:24 hours.

Arthrospira was observed every day until it grows blue green. After growing, *Arthrospira* was re-cultured in agar media by the 4 quadrant scratch method. The cultures were used as isolate samples for determining DNA barcodes.

DNA extraction

DNA extraction was carried out according to procedures in which there was a Presto™ Mini gDNA Bacteria Kit (Geneaid Biotech Ltd.). DNA extraction consisted of several stages: sample preparation, lysis, purification, and precipitation or washing. The sample used was 0.15 grams of wet weight for one extraction.

DNA Amplification

The process of DNA amplification using the PCR (Polymerase Chain Reaction) method was performed using 2 µl forward primers 63f (5'-CAGGCC TAA CAC ATG CAA GTC-3') and reverse primer 1387r (5'-GGG CCG WGT GTA CAA GGC-3') (Marchesi et al., 1998). The total composition of the PCR mixture was 50 µl which consisted of 25 µl Go Taq Green, 13 µl NFW (Nuclease Free Water) and 8 µl *Arthrospira* DNA extraction template. DNA amplification was carried out in stages: the initiation cycle at 95°C for 5 minutes, followed by 30 denaturation cycles at 94 °C for 30 seconds, annealing at 55 °C for 30 seconds, then the extension stage at 72 °C for 1 minute, and the final stage 72 °C for 7 minutes (Lee et al., 2003).

Electrophoresis

Electrophoresis was carried out using 1% agarose gel at 75 V for 35 minutes. Agarose that have been electrophoretic was immersed with a mixture of 10 µl diamond dye solution and 100 ml TAE 1x buffer solution for 30 minutes without exposure to light. The results were visualized through gel documentation by observing DNA migration using a transilluminator UV.

Gene Sequencing

Arthrospira DNA samples that were successfully amplified using PCR were then sequenced in the fragments of 16S rRNA gene. The amplified products were sequenced through the services of the MacroGen Institute in Jakarta. The DNA sequences obtained in the form of fasta format were aligned using MEGA 6.0 software and then uploaded through the Basic Local Alignment Search Tool (BLAST) program. BLAST was a program to search for and analyze the homology of an organism's sequence, on the ncbi.nlm.nih.gov website so that its homology can be identified with other genus *Arthrospira* 16S rRNA gene sequences registered in the GenBank database. The genetic distance and phylogenetic trees between genera were constructed using the Neighbor Joining (NJ) method. The phylogenetic tree was constructed through the Mega 6.0 software application using the Neighbor-Joining (NJ) method of the Maximum Composite Likelihood model and Substitutions to include d: Transitions + Transversions with 1000x bootstrap. Meanwhile *Arthrospira* morphologicals form analysis were presented in the form of images and discussed descriptively by referring to the appropriate literature.

Optimization of pH and salinity for growing *Arthrospira* in Catfish farming wasted water

The experimental design for optimizing pH and salinity media for growing *Arthrospira* in Catfish farming wasted water was a Factorial Completely Randomized Design (CRD) consisting of the first factor with 3 treatments and the second factor with 4 treatments and 3 replications. The first factor was the difference of pH in culture media, including P1: culture media pH 6.5 ± 0.2 , P2: culture media pH 8.5 ± 0.2 and P3: culture media pH 10.5 ± 0.2 . The second factor was the difference of salinity in culture media i.e. S1: salinity of 0 ‰, S2: salinity of 10 ‰, S3: salinity of 20 ‰, and S4: salinity of 30 ‰.

Culture preparation

The equipment used in this study was sterilized using 70% alcohol to minimize the contaminants that inhibit the productivity of *Arthrospira*. The containers used plastic bottles with capacity of 5 L volume of 36 units. The plastic bottle were sterilized using a potassium permanganate solution (2 mg L^{-1}). Catfish culture wastewater obtained from catfish farming ponds measuring 2 m x 1 m x 1 m, and high of water media was 20 cm (Figure 1). The density used in the pond was 330 fish.400 L⁻¹ with 150 grams fish⁻¹, maintained for 2 months by providing artificial feed (protein 31%-33%), twice per day at satiation. Catfish culture wastewater was previously sterilized by boiling in an autoclave and then cooled, while the steril wastewater was treated with salinity. In treatments S1, S2, S3 and S4 were added with salt until salinity was obtained according to the treatment. The wastewater media had a pH of 7.3, therefore there was an addition of HCl 1 N of 0.75 ml L^{-1} in P1 treatment to reach a pH of 6.5. Meanwhile, in treatments P2 and P3, to get a pH of 8.5 and pH 10.5 there was an addition of NaOH 8 N as much as 0.07 ml L^{-1} and 0.45 ml L^{-1} .

Figure 1. Catfish farming pond

Figure 2. *Arthrospira* cultivation

Arthrospira cultivation.

Arthrospira previously used was cultured in catfish culture wastewater for culture stock with a density of 2 g L⁻¹. The stock was taken as much as 400 ml in 3600 ml of catfish culture wastewater in accordance with treatment. Aeration was used for agitation, the lighting using 36 watt TL lamps for 24 hours day⁻¹ during maintenance (Figure 2).

Harvest of biomass.

Harvest of the biomass was after exponential phase by filtering. The biomass was dried using an oven for 14 hours at 40 °C (Afriani et al., 2018 with modification). The dry biomass was used for the phycocyanin extraction process.

Phycocyanin extraction

The dry biomass was 0.04 g added by 1 ml of phosphate buffer pH 7, then homogenized and frozen in the freezer for 24 hours at a temperature of -4 °C. After 24 hours from the freezer, thawing process for 15 minutes. Samples were centrifuged for 30 minutes at 3000 rpm. After that, the sediment and the supernatant were separated. The resulting supernatant was phycocyanin which be analyzed using the Bennett and Bogorad method (1973).

The density of *Arthrospira* biomass.

Biomass density measurements were performed at each treatment and 3 replications every day at the same hour. The density of biomass was 1 ml of sample in each treatment with 3 replications. The 1 ml of sample into aluminum bowl. The sample and the aluminum bowl were weighed, then dried in the oven for 14 hours at 40 °C. The sample of water that had dried was weighed again. The dry biomass weight of *Arthrospira* biomass was converted to g L⁻¹.

Figure 3. Dry biomass of *Arthrospira platensis* after oven

The growth rate of *Arthrospira* can be calculated using the following formula according to Vonshak (1997):

$$\mu = \frac{\ln N_t - \ln N_0}{t} \times 100\%$$

Note : μ = daily growth rate (% days⁻¹)
 t = time (days) from N_0 to N_t
 N_0 = initial density (g L⁻¹)
 N_t = density at the time t (g L⁻¹)

Measurement of total nitrogen and phosphate content in culture media was carried out at the beginning and the first day after the peak phase of each treatment..

The measurement of phycocyanin refers to Bennett and Bogorad (1973). The absorbed supernatant was measured using a spectrophotometer at wavelengths of 615 nm and 652 nm.

$$\text{C-phycocyanin (mg.mL}^{-1}\text{)} = \frac{(\text{OD } 615) - 0.474 (\text{OD } 652)}{5.34}$$

$$\text{Rendement of phycocyanin (mg g}^{-1}\text{)} = \frac{\text{C-phycocyanin} \times \text{V}}{\text{DB}}$$

$$\text{Rendement percentage of phycocyanin (\%)} = \text{Rendement of phycocyanin (mg g}^{-1}\text{)} \times 100\%$$

Note : C-phycocyanin = C-phycocyanin concentration (mg. mL⁻¹)

V = Solvent Volume (ml)

DB = Dry Biomass (0.04 g)

0.474 and 5.34 = coefficient of extinction (Bennett and Bogorad, 1973)

The results were submitted to simple analysis of variance tests (ANOVA) (p <0.05) and in the case of significant differences, the means were compared by the Least Significant Differences test (p<0.05).

RESULTS AND DISCUSSION

Morphology of *Arthrospira*

Arthrospira was cultivated using two different fertilizer media namely technical fertilizer and waste media. The morphology of commercial *Arthrospira* before fertilizer treatment was presented in Figure 4.

Figure 4. Morphological identification results of *Arthrospira* isolate (CA =Commercial *Arthrospira* ; AF= commercial *Arthrospira* cultured with technical fertilizer media; AW= commercial *Arthrospira* cultured with waste media) 40x magnification

The results of the identification of isolates showed that the isolate had a twisted filament shape resembling a spiral (helical). Based on Davis's identification book (1955), it is known that the isolate used in the study was *Spirulina (Arthrospira) platensis*. *Arthrospira* is cyanobacteria belonging to the order Oscillatoriales which has a filament (trichome) that resembles a spiral (helical) but does not have heterocyst cells (Sze, 1998). Heterocyst cells are special thick-walled cells that play a role in nitrogen fixation from the air (Fogg et al., 1979). In this study *Arthrospira* cultured in different media had several linear/straight morphologies.

Based on Figure 2, *Arthrospira* which was cultured on technical fertilizer media has a longer and spiraling morphological form compared to another cultured on waste media. Their filaments have more linear morphological form, some spirals but not too long. According to Astiani et al (2016), *Arthrospira* growth is influenced by nutritional and environmental factors. Wang and Zhao (2005) explained that linearization that occurs in *Arthrospira* is a variation on the genetic level that can be caused by environmental factors such as lack of nutrition and high light intensity. In this study, isolates were cultured with the same light intensity of 2000-3000 lux with a light dark ratio of 0:24 hours.. Linear filaments in AW have a lower metabolic rate compared to

helical filaments. This is one of the adaptive mechanisms for *Arthrospira* to survive some environmental conditions that are not appropriate.

Phylogenetic Tree

The results of the 16S rRNA encoding gene sequences from AF and AW isolates were traced to other *Arthrospira* isolates present in GenBank through the BLAST program. The results of the BLASTn analysis of *Arthrospira* samples cultivated in technical fertilizer and waste media with data in Genbank are presented in Table 1. Table 1 results of the BLAST analysis show the closeness between AF and AW isolates with other isolates in GenBank. It show that *Arthrospira* technical fertilizer isolates and *Arthrospira* waste isolates have the closest homology to *Arthrospira platensis* petH species from Japan with percentage values respectively 100% and 94.3%.

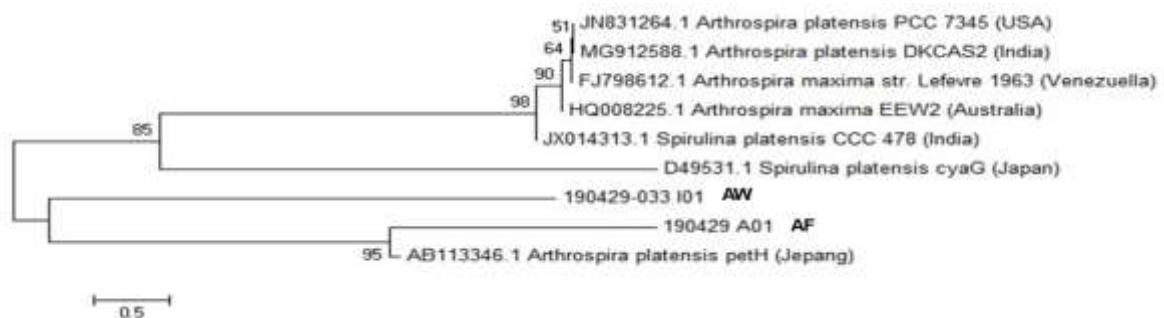

Figure 5. Phylogenetic analysis with 1000 bootstrap AW (*Arthrospira* cultured in waste water media) and AF (*Arthrospira* cultured in fertilizer media)

Genetic distance was used to see kinship relationships from *Arthrospira* both AF and AW samples with sequential data from Genbank. AF isolate indicated a genetic distance of 0.068 with AW isolates. AW and AF isolates showed the lowest genetic distance respectively 0.089 and 0.060 with *Arthrospira platensis* petH from Japan. Analysis based on genetic distance showed that both isolates were belong to the same species namely *Spirulina platensis*, however the genetic distance was 0.068 (6.8%) meaning that there are intraspecies variations in the sample caused by mutations.

Phylogenetic tree *Arthrospira* isolates from technical fertilizer and waste media were presented in Figure 5. The phylogenetic tree is a two-dimensional graph showing relationships between organisms or population classifications based on their evolutionary history. The result of phylogenetic tree construction showed that both samples formed branches with a cluster. Phylogenetic tree from AF and AW isolate sequences formed cluster was separate with several other *Arthrospira* species from GenBank data.

The AF isolates had a close relationship with *Arthrospira platensis* petH species from Japan with a bootstrap value of 95%. Hadiati (2003) states that bootstrap analysis is performed to determine the level of confidence in grouping. Bootstrap value is considered high because according to Hall (2001), a clade can be trusted with a bootsratp value of 90%. In addition, Hillis and Bull (1993) state that bootstrap analysis with values of 70% or higher indicate a reliable grouping. The AW isolates formed a separate brach of AF isolates and

Arthrospira platensis peth species. Genetically, they had diverse, and adapted to environmental conditions. The AW isolate indicated different strain from AF isolate groups. Ballot et al. (2004) stated that *Spirulina* from the same species and cultured under different conditions can form a separate subcluster with a bootstrap value of 79%. Zhao et al. (2006) identified and analyzed the number of restriction-modification genes in the cyanobacterial genome, seeing that more restriction-modification genes were found in cyanobacterial filaments (*Anabaena*, *Spirulina* and *Nostoc*) than dispenses (*Synechocystis*, *Synechococcus* and *Prochlorococcus*) this was due to the organism adapting to various environmental conditions, or the many variations in sources of nutrients that cause mutations.

Density and Growth Rate of *Arthrospira* cultured in wastewater of catfish farming

The biomass of *Arthrospira* displayed mechanism of adaptation in culture media. The wastewater media could make different characteristic of growth as like as filament. The maximum densities of *Arthrospira* cultured in wasted water were achieved on a different day. The daily density of *Arthrospira* during culture can be seen in Figure 6. Biomass density (g.L⁻¹)

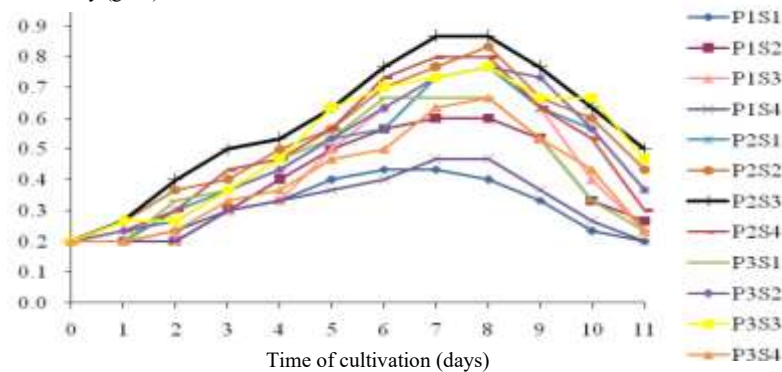

Figure 6. Cell density (dry weight with a moisture content of 1.2%) of *Arthrospira* in catfish rearing pond waste water

The graph presented in Figure 6, it show that in the culture period from day 1 to day 2, *Arthrospira* in each treatment experienced slow growth, because the cells were still adapting to their new environment. The exponential phase for the treatment of P2S2, P2S3, and P3S3 last from day 1 to day 8 of the culture period. In the treatment of P2S1, P2S4, P3S1 and P3S2 take place from 2nd until 8th day of the culture period. While the treatment of P1S1, P1S2, P1S3, P1S4, and P3S4 lasted from 3rd – 8th day of the culture period. The decreasing *Arthrospira* density for the treatment occurred from the day 9 to the day 11 of the culture. Lesmana et al. (2019) explained that the adaptation phase lasts from day 0 to day 1, while the exponential phase occurs from day 1 to day 7, and experiences a stationary phase from day 7 to day 9 then enters the death phase after the 7th day and 9th day. The decrease of density could because of reducing the nutrients in the culture media. Soni et al. (2019), the concentration of nutrients in the media decreased after reaching the peak period. This is due to the higher density of *Arthrospira* in the culture media.

The maximum density of *Arthrospira* could be achieved on different day, between 5 – 8 days after culturing. The mean of maximum density could be 0.433-0.867 g L⁻¹ of dry biomass which cultured in catfish rearing waste water. The maximum cellular density of *A. platensis* which cultured in Nile fish rearing waste water, resulted in the production of 0.22 g L⁻¹ of dry biomass and maximum productivity of 0.03 g L⁻¹ day⁻¹ (Nogueira et al, 2018). The catfish rearing pond waste water has high potential as cultivation media for *Arthrospira* production.

The analysis of variance showed that differences in pH, salinity and interaction between factors (pH and salinity) significantly affect the maximum density and growth rate of *Arthrospira platensis*. The results of the LSD_{0.05} maximum density test and growth rate sequentially were presented in Table 1 and Table 2. LSD_{0.05} test results on the main factors of differences in pH, density and growth rate of *Arthrospira platensis* in the P2 treatment (pH 8.5 ± 0.2) were significantly higher than those in the P1 (pH 6.5 ± 0.2) and P3 treatments (pH 10.5 ± 0.2). According to Ismaiel (2016), the highest biomass of *Arthrospira platensis* is produced in media with a pH of 8.5-9.5. Although *Arthrospira platensis* can tolerate a wide pH range, a pH range farther from its optimal pH can reduce its growth rate. A low growth rate will also cause low biomass production.

Furthermore, the different salinity treatment factors showed that the maximum density and growth rate in treatment S3 (salinity of 20 ‰) were significantly higher compared to S1 (salinity of 0 ‰), S2 (salinity of 10 ‰) and S4 (salinity of 30 ‰) treatments. The S1 and S4 treatments were not significantly different and were the treatments that produced the lowest density compared to other treatments. Table 1 and Table 2 showed that the

highest density and daily growth rate was found in the S3 (salinity of 20 ‰) treatment. This is supported by the results of Kouhgard et al. (2015), that *Arthrospira platensis* cultured on Conway media was able to produce the highest density of 912.07 mL⁻¹ cells at a salinity of 20 ‰. While the density and growth rate between S1 and S4 treatments showed no significant difference. This is because the salinity of 0-30 ‰ is still within the range of salinity that can be tolerated by *Arthrospira*. Ughy et al. (2015) said that *Arthrospira platensis* is one of the species of *Cyanobacteria* that can grow in an euryhaline environment.

Table 1 Maximum density of *Arthrospira platensis* (g L⁻¹)

Single Influence of pH (P)	Single Influence of Salinity (S) (LSD _{0,05} = 0.107)				Main influence of pH (P) (LSD _{0,05} =0.053)
	S1(0 ‰)	S2 (10 ‰)	S3 (20 ‰)	S4 (30 ‰)	
P1 (pH 6.5)	0.433 ^a	0.633 ^b	0.767 ^{cdef}	0.467 ^a	0.575 ^a

The interaction between pH and salinity factors showed that the density and growth rate in treatment P2S3 (pH 8.5 ± 0.2 and salinity of 20 ‰) were significantly higher compared to other treatments. At maximum density, treatment P2S3 was not significantly different from treatments such as P1S3, P2S1, P2S2, P2S4, and P3S3. While in the growth rate, treatment P2S3 was not significantly different from P1S3, P2S2, P2S4, P3S2 and treatments P3S3. Table 1 and Table 2 show that treatment P2 (pH 8.5 ± 0.2) is more dominant causing higher density and growth rate of *Arthrospira platensis* despite being in different salinity ranges. As for the treatments P1 (pH 6.5 ± 0.2) and P3 (pH 10.5 ± 0.2) provide the highest density when combined by the treatment S3 (salinity 20 ppt). The treatment of P1, P2, and P3 (pH 6.5 ± 0.2, 8.5 ± 0.2, and 10, 5 ± 0.2) and S1, S2, S3 and S4 treatments (salinity of 0 ‰, 10 ‰, 20 ‰, and 30 ‰) still support the growth of *Arthrospira platensis* with the best treatment found in the combined treatment P2S3 (pH 8.5 ± 0.2 with salinity of 20 ‰).

Mismatch of pH will cause lysis and can change the shape of pigment growth (Hariyati, 2008). The process of photosynthesis affects the pH value. In daylight, aquatic plants release carbon dioxide from water for use in photosynthesis. The release of carbon dioxide by plants occurs through respiration. When carbon dioxide is released, carbonate builds up and hydrolyzed so that the pH of the water will increase (Boyd, 1990). Prasadi (2018) showed that growth of *Arthrospira* could be inhibited if it was in the pH range above 10.5 or less than 7. Salinity is one of the factors that can influence osmotic pressure for *Arthrospira* as like as others of microalgae. Pisal and Lele (2005) microalgae can experience cell shrinkage in conditions outside the cell salinity higher than inside the cell (hypertonic), and vice versa under conditions of low salinity outside the cell (hypotonic) cell swelling will occur due to water molecules outside moves into the cell. This condition affects the process of photosynthesis, and makes microalgae to produce secondary metabolites in the form of β-carotene to sustain life against changes in salinity in culture media. While in isotonic conditions, cell fluid is isotonic to its external media which causes low active ion transport and osmoefector exchange, making the Na-K-ATPase enzyme activity at a maximum level and more energy will be utilized for growth (Rahmawati et al., 2012). The optimal combination of pH and salinity causes the growth of *Arthrospira* to be maximal. The optimal salinity range for *Arthrospira* is between 15-20 ‰, from the related research showed that the results of *Arthrospira* culture with 20 ‰ of media salinity, pH 7.5-8.5 using fertilizer media (0.010 g L⁻¹ TSP, 0.030 g L⁻¹ Urea, and 0.030 g L⁻¹ ZA) and a culture periode of 9 days produced a dry weight of *Arthrospira* of 0.0375 g L⁻¹ (Prasadi, 2018).

Rendement of phycocyanin

The rendement of *Arthrospira* was presented in Table 3. The pH condition of maintenance media can be affect of protein content in *Arthrospira* cells. The results of LSD_{0.05} on the main factor of pH showed that the rendement of phycocyanin *Arthrospira* in treatment P2 was significantly higher compared to other treatments. Taufiqurrahmi et al. (2017), the amount of *Arthrospira* biomass influences the high content of phycocyanin. Table1 showed that the highest of *Arthrospira* biomass was found in treatment P2. It showed that the highest *Arthrospira* biomass produced the highest rendement of phycocyanin (Table 3). The culture medium of *Arthrospira* pH of 8.5 produced the highest C-phycocyanin content (Ismail et al., 2016). Rahmawati et al. (2017) said that the higher of C-phycocyanin followed the higher of rendement of phycocyanin.

LSD_{0.05} showed that the main factor of salinity showed the rendement of phycocyanin in treatment S3 (salinity of 20 ‰) was significantly higher than other treatments. It is thought that the difference in salinity treatment has an impact on the external osmotic pressure of *Arthrospira* cells which results in changes in cell composition especially phycocyanin. Sodium will flow into the cell and cause the release of phycobilin (phycoeritrin, phycocyanin and allophycocyanin) from PS II (Photosystem II) and stop the electrons transporting to PS I (Photosystem I) followed by activation of the protective mechanism. *Arthrospira* will produce carbohydrates to balance intracellular osmotic pressure and require more energy to remove sodium ions from cells. In this case it will produce ammonium assimilation causes inhibition of protein synthesis (Zhou et al., 2017).

Table 3 Phycocyanin (%) yield in *Arthrospira* dry biomass at 8 days after inoculation

Single Influence of pH (P)	Single Influence of Salinity (S) (LSD _{0.05} = 0.194)				Main influence of pH (P) (LSD _{0.05} =0.096)
	S1	S2	S3	S4	
P1	7.881 ^a	8.783 ^c	9.441 ^d	8.387 ^b	8.623 ^a
P2	9.657 ^c	10.906 ^h	11.347 ⁱ	10.423 ^g	10.583 ^c
P3	8.970 ^c	9.408 ^d	10.134 ^f	9.262 ^d	9.444 ^b
Main influence of Salinity (S) (LSD _{0.05} =0.111)	8.836 ^a	9.699 ^c	10.307 ^d	9.357 ^b	

The environment includes the availability of nutrients, pH, salinity, light and temperature can affect the growth and accumulation of biopigments from microalgae (Sharma and Tiwari, 2014). The condition of culture media is able to influence the growth phase of *Arthrospira*, causing changes in the composition and proportion of phycobilin (phycoeritrin, phycocyanin and allophycocyanin) (Simeunovic et al., 2013). The results of the LSD_{0.05} was showed that the rendement of phycocyanin *Arthrospira* on the interaction between factors in treatment P2S3 was significantly higher than in other treatments, but it was not significantly different from treatment P2S2. This showed from the density and growth rate of *Arthrospira*. The increasing salinity will cause maintenance media to be hypertonic towards cells and result in poor absorption of nutrients by cells. These cells could reduce in protein and increase in carbohydrates from *Arthrospira* cells (Ravelonandro et al., 2011).

Production of phycocyanin was able to reach 12.4 % - 17.6% of biomass dry weight of *Arthrospira* cultured in Zarrouk Medium (ZM) (Prates et al., 2018; Garcia-Lopez et al., 2020). There are several factors that affect the rendement of phycocyanin include temperature, extraction time, mixing rate, biomass, type of solvent and the ratio of biomass to the solvent (Taufiqurrahmi et al., 2016). The content of phycocyanin in cyanobacteria increases when grown in low light intensity. Phycocyanin is a pigment associated with protein, polar and water soluble. The protein content of microalgae are influenced by environmental conditions such as temperature, age of culture, light intensity, pH, salinity, and nutrient limits (especially nitrogen). Nitrogen is an essential element needed for the synthesis of accessory pigments and chlorophyll. When microalgae are growing fast, it requires large amounts of nitrogen and could consume phycocyanin as an alternative source of nitrogen for the production of biomass (Hsieh-Lo et al., 2019). It must be optimized for biomass production and phycocyanin content. The higher concentration of phycocyanin will be followed by the rendement of phycocyanin. In this study, the phycocyanin content is lower than previous study, because of different media for culturing *Arthrospira*. The nutrient from ZM (pro analysis substances) is more complete for growing and forming phycocyanin than waste water catfish pond media, especially the trace mineral in ZM.

Reduction of Total Nitrogen and Phosphate Content

The percentage reduction of total nitrogen in the culture media was presented in Table 4.

Table 4 Reduction of total nitrogen content in *Arthrospira* culture medium (%)

Single Influence of pH (P)	Single Influence of Salinity (S) (LSD _{0.05} = 1.290)				Main influence of pH (P) (LSD _{0.05} =0.645)
	S1	S2	S3	S4	
P1	80.990 ^a	82.250 ^{ab}	83.767 ^{cde}	81.897 ^{ab}	82.226 ^a
P2	83.880 ^{de}	84.377 ^{ef}	85.420 ^f	84.857 ^{ef}	84.633 ^c
P3	82.940 ^{bcd}	81.143 ^a	84.950 ^{ef}	84.813 ^{ef}	83.462 ^b
Main influence of Salinity (S) (LSD _{0.05} =0.745)	82.590 ^a	83.856 ^b	84.712 ^c	82.603 ^a	

The mechanism for removing nitrogen in water is determined by several factors, including bacterial activity (Gersberg et al., 1986), uptake by plants (Breen, 1990) and evaporation (Sanchez-Monedero et al., 2001). In Cyanobacteria, nitrogen is a macronutrient that plays an important role in the formation of biochemical compounds such as nucleic acids (DNA, RNA), amino acids (protein) and pigments (chlorophyll and phycocyanin) (Markou et al., 2014). The results of the LSD_{0.05} on the main pH factor showed that the reduction in total nitrogen content in *Arthrospira* culture media in treatment P2 was significantly higher than in treatments P1 and P3. This is due to the higher density of *Arthrospira* in treatment P2 compared to other treatments, so that the utilization of nitrogen by *Arthrospira* in culture media is greater than others. Markou et al. (2014) showed that the higher density of *Arthrospira* could be higher the absorption of nutrients including nitrogen.

The value of reducing total nitrogen content in S3 treatment was significantly higher than for other treatments. This showed that treatment S3 caused *Arthrospira* to absorb nitrogen higher than other treatments in line with the high density and rendement of phycocyanin *Arthrospira* obtained in this study. Jabeen and Ahmad (2011) showed that salinity in culture media influences nitrogen absorption and protein biosynthesis. Reduction of total nitrogen content in *Arthrospira* culture media due to interactions between pH and salinity factors showed that treatment P2S3 was significantly higher than other treatments. With the optimal conditions (pH and salinity), *Arthrospira* is able to make maximum use of nitrogen. This can be seen from the highest density, growth rate and rendement of phycocyanin found in treatment P2S3. The amount of nitrate and phosphate decreases with increasing growth of *Chlorella vulgaris* and *Arthrospira platensis* (Sayadi et al., 2016). This is because algae have the ability to absorb nutrients such as nitrogen and phosphate are use to carry out photosynthesis and protein production. Reduction of phosphorus content in waters is influenced by the process of absorption, complexation, deposition and assimilation (between microbes and plant biomass) (Tanner et al., 1999).

Table 5 Reduction of phosphate content in *Arthrospira* culture medium (%)

Single Influence of pH (P)	Single Influence of Salinity (S)				Main influence of pH (P)
	S1	S2	S3	S4	
P1	70.500	71.667	73.000	72.333	71.875
P2	74.667	74.000	74.667	72.667	74.000
P3	70.333	70.333	73.667	72.667	71.750
Main influence of Salinity (S)	71.833	72.000	73.778	72.556	

The results of LSD_{0.05} on the main factor of pH showed that each treatment did not significantly affect the reduction of phosphate content in *Arthrospira* culture medium. Plants can only absorb phosphorus in the form of H₂PO₄ and HPO₄²⁻ free orthophosphate ions (Becquer et al., 2014). The orthophosphate content decreases with increasing media pH. Cerozi and Fitzsimmons (2016) showed the orthophosphate content increases in the pH range from 5.5 to 8.5 and decreases when pH 10. The fall in the orthophosphate content at pH 10 is due to an increase in calcium phosphate formation. The value of reducing the phosphate content in *Arthrospira* culture medium was presented in Table 5.

The salinity factor, administration of different salinity in each treatment has no significant effect on reducing the phosphate content. Bassin et al. (2011) explained the reduction of phosphorus will be inhibited when a combination of Cl^- and nitrite and Cl^- concentration more than 2.5 g L^{-1} . The interaction effect of differences in pH and salinity, each treatment had no significant effect on reducing phosphate content. Hua-Sheng et al. (1995) showed that the utilization of Dissolved Organic Phosphorus (DOP) can be through active uptake into cells or by extracellular mineralization by phosphatase enzymes. However, most DOP compounds cannot be assimilated directly with microalgae because they have been mineralized. Markou *et al.* (2014) stated that phosphorus is a macronutrient that plays an important role in the preparation of nucleic acids (RNA and DNA), phospholipids and energy-carrying molecules (ATP). The phosphorus content in plants is lower than Ca, N, and K (Sasaqi et al., 2018). Although the analysis of variance shows that the results are not significantly different, but the highest phosphate reduction still existed in treatment P2S3.

Morphology of *Arthrospira* in various pH and salinity media

Morphology of *Arthrospira* was affected by increasing or decreasing physical or chemical factors in their culture media. Salinity and acidity value combination at this study didn't change the filament of *Arthrospira* significantly as their filament of *Arthrospira* under microscope with 100x magnification (Figure 7). The morphological form of *Arthrospira* were not different in all of pH and salinity treatments. The waste water catfish pond media could affected in the linierizing filament. This study indicated that salinity and acidity of culture media didn't effect on various form filament, either straight and helical.

The straight filaments were observed for *Arthrospira* strains during two years of cultivation, and their presence in *Arthrospira* sp. Nigrita C1 cultures was constant. The various morphological plasticity, greatly influenced by the growth stage and exogenous parameters, such as temperature and light intensity, was observed for *Arthrospira* strains (Papapanagiotou and Gkelis, 2019). There are indications that adaptability to change in environmental conditions is relatively rapid and also subsequent changes at the genetic level can be realized quickly. This means that we can easily find different genotypes in various stable, ecologically different habitats. Morphologically similar strains were cultured for a long time under uniform and stable conditions (Komarek, 2016). But the morphological changes couldnot be effected by acidity and salinity of culture media.

Figure 7. Morphology of *Arthrospira* in catfish wastewater culture media at several treatment of pH and salinity

Conclusions

Arthrospira that is cultured on waste media (observed in liquid culture) indicated some short and linear filaments. Identified *Arthrospira* had a genetic distance of 6.8% between AF and AW isolates. AF isolates had a close relationship with *Arthrospira platensis* petH species originating from Japan (bootstrap value of 95%) while AW isolates form phylogenetic branches which are separated from AF isolates and *Arthrospira platensis* petH species originating from Japan (bootstrap value 85%). The catfish culture wastewater media at different pH and salinity affects the density, growth rate and rendement of phycocyanin *Arthrospira platensis*. The highest density, growth rate and rendement of phycocyanin was in P2S3 treatment (pH 8.5 ± 0.2 and salinity of 20 ‰) which produced a maximum density of 0.867 g L^{-1} , growth rate of $22.026\% \text{ day}^{-1}$ and the rendement of phycocyanin of 11.334 %.

ACKNOWLEDGEMENTS

Reviewer C:

The aim of this study was to characterize the morphological forms and DNA barcode based on 16 rRNA gene of *Spinulina* cultured in fertilizer and waste water effluent of *Clarias* pond farming media and determining optimal pH value and salinity of culture media for growth and C-PC production. The authors carried out so many experiments and analysis and extracted so many data which are appreciated. They worked on morphology of *Arthrospira* cultured with fertilizer and waste water of the fish. they compared the results in some of the characters with each other but in some other characters no.

there are two main problems in this experiment which are:

1- There is no control+/- to compare the results of growth, phyococyanin and identity blasts. The authors need to bring the results of CA (commercial *Arthrospira*) and AF to see the differences between the treatments with Control. the comparison only in morphology has been brought. They should bring this comparison in the other factors they worked like growth, phyococyanin, N and P reduction etc.

2- Still it's not clear how the pH and salinity along with some other factors in the waste water can change genome of an organism during a week.

Recommendation: Revisions Required

Reviewer V:

- What the source of *Arthrospira*?
- Why not use a specific Zarrouk medium?
- In Table 1 and 2

Salinity 10,20 and 30‰ means 100,200 and 30 grams per liter is very high and this under stress which means the reduction of growth rate.

- How is this given growth rate?
- What are the components of wastewater?
- Figures 4 is not clear, should be redrawn for high quality.
- 7- Attention to references

8 - There are some notes in the text

Recommendation: See Comments

Characterization of *Arthrospira platensis* cultured in waste water of *Clarias* catfish farming media: DNA barcode, helical form, growth, and phycoerythrin

Abstract. *Arthrospira* production technology in catfish waste media can be an alternative to reduce environmental pollution. However, some environmental factors such as nutrition, light and water content can influence characterization of *Arthrospira* at the genetic and physiologic level. *Arthrospira platensis* is one of the phycoerythrin-producing cyanobacteria and can be cultured using catfish culture wastewater. Waste quality especially pH and salinity can effect of growth rate and rendement of phycoerythrin from *Arthrospira platensis*. This study aimed to identify the species and morphological forms of *Arthrospira* cultured using technical fertilizer and waste media, as well as to know the phylogenetic trees between species in this study and the GenBank based on the 16S rRNA gene, and determine the optimum of pH and salinity required in the medium of catfish culture wastewater to phycoerythrin maximum production of *Arthrospira*. The optimization of pH and salinity method used Completely Randomized Design (CRD) factorial with 2 factors consisting of the first factor with 3 treatments and the second factor with 4 treatments and 3 replications. The first factor was pH of culture medium i.e. pH 6.5 ± 0.2, pH 8.5 ± 0.2 and pH 10.5 ± 0.2. The second factor was salinity of culture medium, that were salinity 0 ppt (per thousand /‰), 10 ppt, 20 ppt and 30 ppt. Parameters observed in *Arthrospira* include density, growth rate, rendement of phycoerythrin, and decreased of total nitrogen and phosphate content in culture media. The results showed that morphology *Arthrospira* cultured on technical fertilizer media (AF) had a longer and helix filament compared to *Arthrospira* cultured on waste media (AW) which showed several linear and shorter filaments. Both samples have a genetic distance of 0.068 (6.8%). Phylogenetic trees indicated that AF had a close relationship with *Arthrospira platensis* p6H1 from Japan (bootstrap value 95%). While AW formed a separate sub cluster of AF isolates and *Arthrospira platensis* p6H1 from Japan (bootstrap value of 85%). The best treatment in this study was P2S3 (pH 8.5 ± 0.2 with salinity 20 ppt), which produced 0.867 grams maximum density, growth rate of 22.026 %/day⁻¹ and 11.347 mg.g⁻¹ rendement of phycoerythrin.

Keywords: catfish culture wastewater, DNA barcode, pH, phycoerythrin, phylogenetic analysis, salinity, *Arthrospira platensis*, 16S rRNA

INTRODUCTION

Arthrospira is a genus of cyanobacterial microalgae, commonly known under the taxonomically incorrect brand name "Spirulina" (Pappapanagiotou & Gkeli, 2019). The cyanobacterial genus *Arthrospira* ~~Spirulina~~ ~~Stäuberger ex Gomont 1892~~ contains at present 23 species, along with 12 infraspecific taxa (Guiry & Guiry, 2018). They have variety characteristic of molecular, morphology, and physiology that based on polyphasic approach. Various genotypes are adaptable to various specialized ecosystems. The combination of different methods should be based on molecular sequencing as the basic approach, to which must be added other criteria (morphological, ecological) if they are available and which are distinct and recognizable in cyanobacterial populations (Komárek, 2016). A polyphasic approach to include all the criteria obtained from morphological, biochemical, molecular studies, and phylogenetic to understand cyanobacterial classification as like as *Arthrospira* classification (Komárek, 2016). Recent studies have shown that *Arthrospira* can be used for treating wastewater, including effluent from fish culture, because the biomass can metabolize the nutrients and remove the ~~environmental~~ from aquaculture effluent efficiently (Zhang et al., 2020). Industrial and processing wastes and by-products for culturing *Spirulina* (*Arthrospira*) are also being considered as alternative culture media, as like as aquaculture waste water (Ragaza et al., 2020, Wijayanti et al., 2018, Widyanoro et al., 2018). Aquaculture could apply an integrated strategy of simultaneously treating aquaculture effluent while producing the biomass to supplement fish diets. The nutrient composition in their biomass depends on their environmental factor for growing biomass. Their character could be different with the various media for growth.

Basically, *Arthrospira*'s morphology is characterized by trichomes that circular regularly (helical). However, abnormal morphology can also occur in *Arthrospira* as a circular shape that is irregular even linear. In some cultivation conditions, linear filaments can spontaneously return to the helix. However, there are significant differences in morphology, ultrastructure, physiology, biochemistry, and genetic characteristics between the original filament and the linear filament but not the difference between the original and the returned filament. Linearization in *Arthrospira* is a variation on the genetic level that can be caused by several environmental factors such as nutrition, light and content of water media for growth (Wang and Zhao 2005). According to Liu et al., (2016), DNA barcoding has developed as a reliable technology for identifying species based on variations in the sequence of standard DNA regions. This method is used successfully in a variety of biological applications including finding cryptic species, detecting invasive species, and identifying plants. DNA barcoding is a simple short genome sequence amplified via PCR using appropriate primers (Adamowicz, 2015). DNA barcoding using the 16S rRNA gene has been widely used to determine bacterial DNA characterization. Therefore, identification of *Arthrospira* using the 16S rRNA gene needs to be done to get the characterization of *Arthrospira* that is cultured on technical fertilizer and waste media and determine the phylogenetic tree structure that has been recorded in GenBank.

Culture of *Arthrospira* (*Spirulina*) in *Clarias* pond farming waste water could have specific characterization for optimal pH value and salinity. Their adaptation to grow in organic waste water make change in bioactive and important compound production. Their biomass has a nutritional value of 55-70% protein, 6-10% lipid, 20% carbohydrate, besides being rich in minerals, vitamins, and pigments (Borowiczka et al., 2016; Veres et al., 2016). Some color pigments that can be produced such as phycoerythrin (blue pigment), allophycoerythrin (blue-green) and phycoerythrin (red pigment) (Sharma and Tiwari, 2011; Veres et al., 2015). Phycoerythrin is pigment in *Arthrospira* which has functions as an antioxidant (Ponnamoorthy and Limanantara, 2008), a source of food coloring, cosmetics, pharmaceuticals and drugs (Tang et al., 2020; Twardi & Twardi, 2020), anti-inflammatory, anti-oxidative and anticancer (Liu et al., 2013). One of the factors that influence phycoerythrin levels is biomass (Fauziah et al., 2017). The pH and salinity of culture media can affect the biomass of *Arthrospira* (Cifani, 1983; Marek et al., 1987; Platas et al., 2002). Imaiel et al. (2016) showed that the diversity of the chemical composition of biomass is influenced by the pH of the growth media. Value of pH and environmental factors, especially salinity, influence the productivity of cell biomass, photosynthesis, shape, and flow of cellular metabolic activity that affect the dynamics of cell composition (Hu, 2004). The optimal pH value for growth of *Arthrospira* sp is 7-10.5 (Hartiyati, 2008), and salinity from 15-30 ‰ (Thajakklin and Subramanian, 2005). The salinity and pH value of *Arthrospira* culture media have been known to affect the morphology of the filament.

The aims of this study is characterizing morphological forms and DNA barcode based on the 16S rRNA gene of *Arthrospira* (*Spirulina*) cultured in fertilizer and waste water effluent of *Clarias* pond farming media, and determining optimal pH value and salinity of culture media for growth and phycoerythrin production, especially in *Clarias* pond farming waste water media and morphological changes of their filament.

MATERIALS AND METHODS

Arthrospira cultured in agar media

Bacto agar was weighed as much as 2 g dissolved in 100 ml of water. The water used was swamp water and catfish culture waste that has been filtered and sterilized using an autoclave. Sterilized swamp water was then added with 0.02 gram MgSO₄ fertilizer; CaCl₂ 0.004 gram; EDTA 0.008 gram; urea 0.03 gram; ZA (definitum) 0.132 grams; 0.4 gram baking soda; AB solution 1 ml (A solution (1g ammonium) 20 grams / 100 ml B solution (1g ammonium) 20 grams/100 ml water) and TSP (definitum) 0.05 grams were then homogeneous using magnetic stirrer. Next, waste water was sterilized by an autoclave then cooled. Bactoagar was added to the technical fertilizer and waste solution to be homogenized using a magnetic stirrer and then boiled using a hot plate until all the ingredients dissolve and then autoclave again. The agar media was made with a pH of 7 and a salinity of 10 or 1.0 g.L⁻¹. *Arthrospira* cultivated in liquid media was taken 100 µl using micropipette and spread to the surface of a petri dish containing bactoagar media by using a sterilized spreader rod. Petri dishes were wrapped in wrapping plastic and then given a lamp lighting (light intensity 2000-4000 lux) with a dark: light ratio = 0:24 hours. *Arthrospira* was observed every day until it grows blue green. After growing, *Arthrospira* was re-cultured in agar media by the 4 quadrant scratch method. The cultures were used as isolate samples for determining DNA barcodes.

What the source of *Arthrospira*?
Why not use a specific Zarnek medium?

DNA extraction

DNA extraction was carried out according to procedures in which there was a Presto TM Mini gDNA Bacteria Kit (Genesee Biotech Ltd.). DNA extraction consisted of several stages: sample preparation, lysis, purification, and precipitation or washing. The sample used was 0.15 grams of wet weight for one extraction. (What is the reference?)

DNA amplification

The process of DNA amplification using the PCR (Polymerase Chain Reaction) method was performed using 2 µl forward primers 63H (5'-CAGGCCC TAA CAC ATG CAA GTC-3') and reverse primer 1387r (3'-GGG CCG WGT GTA CAA GGC-3') (Manishi et al., 1998). The total composition of the PCR mixture was 50 µl which consisted of 25 µl Go Taq Green, 13 µl NFW (Nuclease Free Water) and 8 µl *Arthrospira* DNA extraction template. DNA amplification was carried out in stages: the initiation cycle at 95°C for 5 minutes, followed by 30 denaturation cycles at 94°C for 30 seconds, annealing at 55°C for 30 seconds, then the extension stage at 72°C for 1 minute, and the final stage 72°C for 7 minutes (Lee et al., 2003).

Electrophoresis

Electrophoresis was carried out using 1% agarose gel at 75 V for 35 minutes. Agarose that have been electrophoretic was immersed with a mixture of 10 µl diamond dye solution and 100 ml TAE 1x buffer solution for 30 minutes without exposure to light. The results were visualized through gel documentation by observing DNA migration using a transilluminator UV.

Gene Sequencing

Arthrospira DNA samples that were successfully amplified using PCR were then sequenced in the fragments of 16S rRNA gene. The amplified products were sequenced through the services of the Macrogen Institute in Jakarta. The DNA sequences obtained in the form of fasta format were aligned using MEGA 6.0 software and then uploaded through the Basic Local Alignment Search Tool (BLAST) program. BLAST was a program to search for and analyze the homology of an organism's sequence, on the ncbi.nlm.nih.gov website so that its homology can be identified with other genus *Arthrospira* 16S rRNA gene sequences registered in the GenBank database. The genetic distance and phylogenetic trees between genera were constructed using the Neighbor Joining (NJ) method. The phylogenetic tree was constructed through the Mega 6.0 software application using the Neighbor-Joining (NJ) method of the Maximum Composite Likelihood model and Substitutions to include δ : Transitions + Transversions with 1000s bootstrap. Meanwhile *Arthrospira* morphologicals form analysis were presented in the form of images and discussed descriptively by referring to the appropriate literature.

Optimization of pH and salinity for growing *Arthrospira* in Catfish farming wastewater
The experimental design for optimizing pH and salinity media for growing *Arthrospira* in Catfish farming wastewater was a Factorial Completely Randomized Design (CRD) consisting of the first factor with 3 treatments and the second factor with 4 treatments and 3 replications. The first factor was the difference of pH in culture media, including P1: culture media pH 6.5 \pm 0.2, P2: culture media pH 8.5 \pm 0.2 and P3: culture media pH 10.5 \pm 0.2. The second factor was the difference of salinity in culture media i.e. S1: salinity of 0‰, S2: salinity of 10‰, S3: salinity of 20‰, and S4: salinity of 30‰. (What is the type of salt?)

Culture preparation

The equipment used in this study was sterilized using 70% alcohol to minimize the contaminants that inhibit the productivity of *Arthrospira*. The containers used plastic bottles with capacity of 5 L volume of 36 units. The plastic bottle were sterilized using a potassium permanganate solution (2 mg L⁻¹). Catfish culture wastewater obtained from catfish farming ponds measuring 2 m x 1 m x 1 m, and high of water media was 20 cm (Figure 1). The density used in the pond was 330 fish/400 L⁻¹ with 150 grams fish⁻¹, maintained for 2 months by providing artificial feed (protein 31%-33%), twice per day at situations. Catfish culture wastewater was previously sterilized by boiling in an autoclave and then cooled, while the steel wastewater was treated with salinity. In treatments S1, S2, S3 and S4 were added with salt until salinity was obtained according to the treatment. The wastewater media had a pH of 7.3, therefore there was an addition of HCl 1 N of 0.75 ml L⁻¹ in P1 treatment to reach a pH of 6.5. Meanwhile, in treatments P2 and P3, to get a pH of 8.5 and pH 10.5 there was an addition of NaOH 8 N as much as 0.07 ml L⁻¹ and 0.45 ml L⁻¹.

Figure 1. Catfish farming pond

Figure 2. *Arthrospira* cultivation

Arthrospira cultivation

Arthrospira previously used was cultured in catfish culture wastewater for culture stock with a density of 2 g L⁻¹. The stock was taken as much as 400 ml in 3600 ml of catfish culture wastewater in accordance with treatment. Aeration was used for agitation, the lighting using 36 watt TL lamps for 24 hours day⁻¹ during maintenance (Figure 2).

Harvest of biomass. (What are the components of wastewater?)

Harvest of the biomass was after exponential phase by filtering. The biomass was dried using an oven for 14 hours at 40 °C (Abiani et al., 2018 not found in the inference, with modification). The dry biomass was used for the phycocyanin extraction process.

Phycocyanin extraction

The dry biomass was 0.04 g added by 1 ml of phosphate buffer pH 7, then homogenized and frozen in the freezer for 24 hours at a temperature of -4 °C. After 24 hours from the freezer, thawing process for 15 minutes. Samples were centrifuged for 30 minutes at 3000 rpm. After that, the sediment and the supernatant were separated. The resulting supernatant was phycocyanin which be analyzed using the Bennett and Bogorad method (1973).

The density of *Arthrospira* biomass

Biomass density measurements were performed at each treatment and 3 replications every day at the same hour. The density of biomass was 1 ml of sample in each treatment with 3 replications. The 1 ml of sample into aluminum bowl. The sample and the aluminum bowl were weighed, then dried in the oven for 14 hours at 40 °C. The sample of water that had dried was weighed again. The dry biomass weight of *Arthrospira* biomass was converted to g L⁻¹.

Figure 3. Dry biomass of *Arthrospira platensis* after oven

The growth rate of *Arthrospira* can be calculated using the following formula according to Vonshak (1997):

$$\mu = \frac{\ln N_t - \ln N_0}{t} \times 100\%$$

Note: μ = daily growth rate (% days⁻¹)
 t = time (days) from N_0 to N_t
 N_0 = initial density (g L⁻¹)
 N_t = density at the time t (g L⁻¹)

Measurement of total nitrogen and phosphate content in culture media was carried out at the beginning and the first day after the peak phase of each treatment.

The measurement of phycocyanin refers to Bennett and Bogorad (1973). The absorbed supernatant was measured using a spectrophotometer at wavelengths of 615 nm and 652 nm.

$$C_{\text{phycocyanin}} (\text{mg mL}^{-1}) = \frac{\text{OD}_{615} - 0.474 (\text{OD}_{652})}{5.34}$$

$$\text{Rendement of phycocyanin} (\text{mg g}^{-1}) = \frac{C_{\text{phycocyanin}} \times V}{\text{DB}}$$

Rendement percentage of phycocyanin (%) = Rendement of phycocyanin (mg g⁻¹) \times 100%

Note: $C_{\text{phycocyanin}}$ = Phycocyanin concentration (mg mL⁻¹)

V = Solvent Volume (ml)

DB = Dry Biomass (0.04 g)

0.474 and 5.34 = coefficient of extinction (Bennett and Bogorad, 1973)

The results were submitted to simple analysis of variance tests (ANOVA) ($p < 0.05$) and in the case of significant differences, the means were compared by the Least Significant Differences test ($p < 0.05$).

221 **RESULTS AND DISCUSSION**

222 **Morphology of *Arthrospira***

223 *Arthrospira* was cultivated using two different fertilizer media namely technical fertilizer and waste media. The morphology of commercial *Arthrospira* before fertilizer treatment was presented in Figure 4.

239 **Figure 4.** Morphological identification results of *Arthrospira* isolate (CA = Commercial *Arthrospira*; AF = commercial *Arthrospira* cultured with technical fertilizer media; AW = commercial *Arthrospira* cultured with waste media) 40x magnification

241 The results of the identification of isolates showed that the isolate had a twisted filament shape resembling a spiral (helical). Based on Davis's identification book (1955), it is known that the isolate used in the study was *Spirulina* (*Arthrospira*) *platensis*. *Arthrospira* is cyanobacteria belonging to the order Oscillatoriales which has a filament (trichome) that resembles a spiral (helical) but does not have heterocyst cells (Sze, 1998). Heterocyst cells are special thick-walled cells that play a role in nitrogen fixation from the air (Fogg et al., 1979, not found in the reference). In this study *Arthrospira* cultured in different media had several linear/straight morphologies.

247 Based on Figure 2, *Arthrospira* which was cultured on technical fertilizer media has a longer and spiraling morphological form compared to another cultured on waste media. Their filaments have more linear morphological form, some spirals but not too long. According to Astiani et al (2016), *Arthrospira* growth is influenced by nutritional and environmental factors. Wang and Zhuo (2005) explained that linearization that occurs in *Arthrospira* is a variation on the genetic level that can be caused by environmental factors such as lack of nutrition and high light intensity. In this study, isolates were cultured with the same light intensity of 2000-3000 lux with a light dark ratio of 0:24 hours. Linear filaments in AW have a lower metabolic rate compared to helical filaments. This is one of the adaptive mechanisms for *Arthrospira* to survive some environmental conditions that are not appropriate.

256 **Table 1.** The results of the BLASTn analysis of *Arthrospira* samples cultivated in technical fertilizer and waste media with data Genbank

Description	Identity (%)	Access code	Sample origin

259 **Phylogenetic Tree**

260 The results of the 16S rRNA encoding gene sequences from AF and AW isolates were traced to other *Arthrospira* isolates present in GenBank through the BLAST program. The results of the BLASTn analysis of *Arthrospira* samples cultivated in technical fertilizer and waste media with data in Genbank are presented in Table 1. Table 1 results of the BLAST analysis show the closeness between AF and AW isolates with other isolates in GenBank. It shows that *Arthrospira* technical fertilizer isolates and *Arthrospira* waste isolates have the closest homology to *Arthrospira platensis* p01H species from Japan with percentage values respectively 100% and 94.3%.

273 **Figure 5.** Phylogenetic analysis with 1000 bootstrap AW (*Arthrospira* cultured in waste water media) and AF (*Arthrospira* cultured in fertilizer media)

275 Genetic distance was used to see kinship relationships from *Arthrospira* both AF and AW samples with sequential data from Genbank. AF isolate indicated a genetic distance of 0.068 with AW isolates. AW and AF isolates showed the lowest genetic distance respectively 0.089 and 0.060 with *Arthrospira platensis* p01H from Japan. Analysis based on genetic distance showed that both isolates were belong to the same species namely *Spirulina platensis*, however the genetic distance was 0.068 (6.8%) meaning that there are intraspecific variations in the sample caused by mutations.

280 Phylogenetic tree *Arthrospira* isolates from technical fertilizer and waste media were presented in Figure 5. The phylogenetic tree is a two-dimensional graph showing relationships between organisms or population classifications based on their evolutionary history. The result of phylogenetic tree construction showed that both samples formed branches with a cluster. Phylogenetic tree from AF and AW isolate sequences formed cluster was separate with several other *Arthrospira* species from GenBank data.

285 The AF isolates had a close relationship with *Arthrospira platensis* p01H species from Japan with a bootstrap value of 95%. Hadiati (2003) states that bootstrap analysis is performed to determine the level of confidence in grouping. Bootstrap value is considered high because according to Hall (2001), a clade can be trusted with a bootstrap value of 90%. In addition, Hillis and Bull (1993) state that bootstrap analysis with values of 70% or higher indicate a reliable grouping. The AW isolates formed a separate branch of AF isolates and *Arthrospira platensis* p01H species. Genetically, they had diverse, and adapted to environmental conditions. The AW isolate indicated different strain from AF isolate groups. Balkot et al. (2004) stated that *Spirulina* from the same species and cultured under different conditions can form a separate subcluster with a bootstrap value of 79%. Zhao et al. (2006) identified and analyzed the number of restriction-modification genes in the cyanobacterial genome, seeing that more restriction-modification genes were found in cyanobacterial filaments (*Anabaena*, *Spirulina* and *Nostoc*) than dispenses (*Synechocystis*, *Synechococcus* and *Prochlorococcus*) this was due to the organism adapting to various environmental conditions, or the many variations in sources of nutrients that cause mutations.

298 **Density and Growth Rate of *Arthrospira* cultured in wastewater of catfish farming**

299 The biomass of *Arthrospira* displayed mechanism of adaptation in culture media. The wastewater media could make different characteristic of growth as like as filament. The maximum densities of *Arthrospira* cultured in wasted water were achieved on a different day. The daily density of *Arthrospira* during culture can be seen in Figure 6.

Figure 6. Cell density (dry weight with a moisture content of 1.2%) of *Arthrospira* in catfish rearing pond waste water.

The graph presented in Figure 6, it show that in the culture period from day 1 to day 2, *Arthrospira* in each treatment experienced slow growth, because the cells were still adapting to their new environment. The exponential phase for the treatment of P2S2, P2S3, and P3S3 last from day 1 to day 8 of the culture period. In the treatment of P2S1, P2S4, P3S1 and P3S2 take place from 2nd until 8th day of the culture period. While the treatment of P1S1, P1S2, P1S3, P1S4, and P3S4 lasted from 3rd – 8th day of the culture period. The decreasing *Arthrospira* density for the treatment occurred from the day 9 to the day 11 of the culture. Lesmana et al. (2019) explained that the adaptation phase lasts from day 0 to day 1, while the exponential phase occurs from day 1 to day 7, and experiences a stationary phase from day 7 to day 9 then enters the death phase after the 7th day and 9th day. The decrease of density could because of reducing the nutrients in the culture media. Soni et al. (2019), the concentration of nutrients in the media decreased after reaching the peak period. This is due to the higher density of *Arthrospira* in the culture media.

The maximum density of *Arthrospira* could be achieved on different day, between 5 – 8 days after culturing. The mean of maximum density could be 0.433-0.867 g L⁻¹ of dry biomass which cultured in catfish rearing waste water. The maximum cellular density of *A. platensis* which cultured in Nile fish rearing waste water, resulted in the production of 0.22 g L⁻¹ of dry biomass and maximum productivity of 0.03 g L⁻¹ day⁻¹ (Nogueira et al. 2018). The catfish rearing pond waste water has high potential as cultivation media for *Arthrospira* production.

The analysis of variance showed that differences in pH, salinity and interaction between factors (pH and salinity) significantly affect the maximum density and growth rate of *Arthrospira platensis*. The results of the LSD 0.05 maximum density test and growth rate sequentially were presented in Table 1 and Table 2. LSD 0.05 test results on the main factors of differences in pH, density and growth rate of *Arthrospira platensis* in the P2 treatment (pH 8.5 ± 0.2) were significantly higher than those in the P1 (pH 6.5 ± 0.2) and P3 treatments (pH 10.5 ± 0.2). According to Imaniel (2016), the highest biomass of *Arthrospira platensis* is produced in media with a pH of 8.5-9.5. Although *Arthrospira platensis* can tolerate a wide pH range, a pH range farther from its optimal pH can reduce its growth rate. A low growth rate will also cause low biomass production.

Furthermore, the different salinity treatment factors showed that the maximum density and growth rate in treatment S3 (salinity of 20 ‰) were significantly higher compared to S1 (salinity of 0 ‰), S2 (salinity of 10 ‰) and S4 (salinity of 30 ‰) treatments. The S1 and S4 treatments were not significantly different and were the treatments that produced the lowest density compared to other treatments. Table 1 and Table 2 showed that the highest density and daily growth rate was found in the S3 (salinity of 20 ‰) treatment. This is supported by the results of Koutbghani et al. (2015), that *Arthrospira platensis* cultured on Conway media was able to produce the highest density of 912.07 mL⁻¹ cells at a salinity of 20 ‰. While the density and growth rate between S1 and S4 treatments showed no significant difference. This is because the salinity of 0-30 ‰ is still within the range of salinity that can be tolerated by *Arthrospira*. Ugly et al. (2015) said that *Arthrospira platensis* is one of the species of Cyanobacteria that can grow in an arylhaline environment.

Table 1. Maximum density of *Arthrospira platensis* (g L⁻¹)

Single influence of pH (P)	Single Influence of Salinity (S)				Main influence of pH (P)
	S1 (0 ‰)	S2 (10 ‰)	S3 (20 ‰)	S4 (30 ‰)	
P1 (pH 6.5)	0.433 ^a	0.833 ^a	0.707 ^{ab}	0.467 ^a	0.535 ^a
P2 (pH 8.5)	0.767 ^{ab}	0.833 ^a	0.907 ^b	0.800 ^{ab}	0.817 ^a
P3 (pH 10.5)	0.667 ^b	0.733 ^{ab}	0.707 ^{ab}	0.700 ^{ab}	0.717 ^a
Main influence of Salinity (S) (LSD _{0.05} =0.082)	0.622 ^a	0.733 ^b	0.800 ^c	0.656 ^a	

Table 2. The growth rate of *Arthrospira platensis* cultured in pH and salinity treatment (% day⁻¹)

Single influence of pH (P)	Single Influence of Salinity (S)				Main influence of pH (P)
	S1 (0 ‰)	S2 (10 ‰)	S3 (20 ‰)	S4 (30 ‰)	
P1 (pH 6.5)	14.333 ^a	18.650 ^{ab}	19.192 ^{ab}	13.548 ^a	16.383 ^a
P2 (pH 8.5)	18.343 ^{ab}	20.570 ^{ab}	22.026 ^b	20.723 ^{ab}	20.416 ^a
P3 (pH 10.5)	20.023 ^{ab}	19.527 ^{ab}	20.623 ^{ab}	16.417 ^{ab}	19.147 ^a
Main influence of Salinity (S) (LSD _{0.05} =1.861)	17.566 ^a	19.585 ^b	20.614 ^b	16.829 ^a	

In Table 1 and 2

Salinity 10, 20 and 30 ‰ means 100, 200 and 300 ppm per liter is very high and this under stress which means reduce of growth rate.

How is this given growth rate?

The interaction between pH and salinity factors showed that the density and growth rate in treatment P2S3 (pH 8.5 ± 0.2 and salinity of 20 ‰) were significantly higher compared to other treatments. At maximum density, treatment P2S3 was not significantly different from treatments such as P1S3, P2S1, P2S2, P2S4, and P3S3. While in the growth rate, treatment P2S3 was not significantly different from P1S3, P2S2, P2S4, P3S2 and treatments P3S3. Table 1 and Table 2 show that treatment P2 (pH 8.5 ± 0.2) is more dominant causing higher density and growth rate of *Arthrospira platensis* despite being in different salinity ranges. As for the treatments P1 (pH 6.5 ± 0.2) and P3 (pH 10.5 ± 0.2) provide the highest density when combined by the treatment S3 (salinity 20 ppt). The treatment of P1, P2, and P3 (pH 6.5 ± 0.2, 8.5 ± 0.2, and 10.5 ± 0.2) and S1, S2, S3 and S4 treatments (salinity of 0 ‰, 10 ‰, 20 ‰, and 30 ‰) still support the growth of *Arthrospira platensis* with the best treatment found in the combined treatment P2S3 (pH 8.5 ± 0.2 with salinity of 20 ‰).

Mismatch of pH will cause lysis and can change the shape of pigment growth (Hariyati, 2008). The process of photosynthesis affects the pH value. In daylight, aquatic plants release carbon dioxide from water for use in photosynthesis. The release of carbon dioxide by plants occurs through respiration. When carbon dioxide is released, carbonate builds up and hydrolyzed so that the pH of the water will increase (Boyd, 1990). Prasad (2018) showed that growth of *Arthrospira* could be inhibited if it was in the pH range above 10.5 or less than 7. Salinity is one of the factors that can influence osmotic pressure for *Arthrospira* as like as others of microalgae. Pisal and Lele (2005) microalgae can experience cell shrinkage in conditions outside the cell salinity higher than inside the cell (hypertonic), and vice versa under conditions of low salinity outside the cell (hypotonic) cell swelling will occur due to water molecules outside moves into the cell. This condition affects the process of photosynthesis, and makes microalgae to produce secondary metabolites in the form of β-carotene to sustain life against changes in salinity in culture media. While in isotonic conditions, cell fluid is isotonic to its external media which causes low active ion transport and osmofector exchange, making the Na-K-ATPase enzyme activity at a maximum level and more energy will be utilized for growth (Rahmawati et al., 2012). The optimal combination of pH and salinity causes the growth of *Arthrospira* to be maximal. The optimal salinity range for *Arthrospira* is between 15-20 ‰, from the related research showed that the results of *Arthrospira* culture with 20 ‰ of media salinity, pH 7.5-8.5 using fertilizer media (0.010 g L⁻¹ TSP, 0.030 g L⁻¹ Urea, and 0.030 g L⁻¹ ZA) and a culture periode of 9 days produced a dry weight of *Arthrospira* of 0.0375 g L⁻¹ (Prasadi, 2018).

Remedment of phycoyanin

The remedment of *Arthrospira* was presented in Table 3. The pH condition of maintenance media can be affect of protein content in *Arthrospira* cells. The results of LSD 0.05 on the main factor of pH showed that the remedment of phycoyanin *Arthrospira* in treatment P2 was significantly higher compared to other treatments. Taufiqurrahmi et al. (2017), the amount of *Arthrospira* biomass influences the high content of phycoyanin. Table1 showed that the highest *Arthrospira* biomass was found in treatment P2. It showed that the highest *Arthrospira* biomass produced the highest remedment of phycoyanin (Table 3). The culture medium of *Arthrospira* pH of 8.5 produced the highest C-phycoyanin content (Imanuel et al., 2016). Rahmawati et al. (2017) said that the higher of C-phycoyanin followed the higher of remedment of phycoyanin.

LSD 0.05 showed that the main factor of salinity showed the remedment of phycoyanin in treatment S3 (salinity of 20 ‰) was significantly higher than other treatments. It is thought that the difference in salinity treatment has an impact on the external osmotic pressure of *Arthrospira* cells which results in changes in cell composition especially phycoyanin. Sodium will flow into the cell and cause the release of phycoobilin (phycoeritrin, phycoyanin and allophycoyanin) from PS II (Photosystem II) and stop the electrons transporting to PS I (Photosystem I) followed by activation of the protective mechanism. *Arthrospira* will produce carbohydrates to balance intracellular osmotic pressure and require more energy to remove sodium ions from cells. In this case it will produce ammonium assimilation causes inhibition of protein synthesis (Zhao et al., 2017).

Table 3. Phycoyanin (%) yield in *Arthrospira* dry biomass at 8 days after inoculation

Single influence of pH (P)	Single Influence of Salinity (S)				Main influence of pH (P)
	S1	S2	S3	S4	
P1	7.881 ^a	8.783 ^a	9.441 ^a	8.387 ^a	8.623 ^a
P2	9.657 ^a	10.906 ^b	11.347 ^b	10.423 ^a	10.283 ^a
P3	8.970 ^a	9.408 ^a	10.134 ^a	9.262 ^a	9.444 ^a
Main influence of Salinity (S) (LSD _{0.05} =0.111)	8.836 ^a	9.699 ^b	10.307 ^b	9.357 ^a	

The environment includes the availability of nutrients, pH, salinity, light and temperature can affect the growth and accumulation of biopigments from microalgae (Sharma and Tiwari, 2014). The condition of culture media is able to influence the growth phase of *Arthrospira*, causing changes in the composition and proportion of phycoobilin (phycoeritrin, phycoyanin and allophycoyanin) (Simunovic et al., 2013). The results of the LSD 0.05 was showed that the remedment of phycoyanin *Arthrospira* on the interaction between factors in treatment P2S3 was significantly higher than in other treatments, but it was not significantly different from treatment P2S2. This showed from the density and growth rate of *Arthrospira*. The increasing salinity will cause maintenance media to be hypertonic towards cells and result in poor

412 absorption of nutrients by cells. These cells could reduce in protein and increase in carbohydrates from *Arthrospira* cells
 413 (Ravelomanandro et al., 2011).
 414 Production of phycoerythrin was able to reach 12.4 % - 17.6% of biomass dry weight of *Arthrospira* cultured in Zarrouk
 415 Medium (ZM) (Potes et al., 2018; Garcia-Lopez et al., 2020). There are several factors that affect the rendement of
 416 phycoerythrin include temperature, extraction time, mixing rate, biomass, type of solvent and the ratio of biomass to the
 417 solvent (Taufiqurrahmi et al., 2016). The content of phycoerythrin in cyanobacteria increases when grown in low light
 418 intensity. Phycoerythrin is a pigment associated with protein, polar and water soluble. The protein content of microalgae
 419 are influenced by environmental conditions such as temperature, age of culture, light intensity, pH, salinity, and nutrient
 420 limits (especially nitrogen). Nitrogen is an essential element needed for the synthesis of accessory pigments and
 421 chlorophyll. When microalgae are growing fast, it requires large amounts of nitrogen and could consume phycoerythrin as
 422 an alternative source of nitrogen for the production of biomass (Hsieh-Lo et al., 2019). It must be optimized for biomass
 423 production and phycoerythrin content. The higher concentration of phycoerythrin will be followed by the rendement of
 424 phycoerythrin. In this study, the phycoerythrin contents is lower than previous study, because of different media for culturing
 425 *Arthrospira*. The nutrient from ZM (pro analysis substances) is more complete for growing and forming phycoerythrin than
 426 waste water catfish pond media, especially the trace mineral in ZM.

427 **Reduction of Total Nitrogen and Phosphate Content**
 428 The percentage reduction of total nitrogen in the culture media was presented in Table 4.
 429

430 **Table 4. Reduction of total nitrogen content in *Arthrospira* culture medium (%)**

Single Influence of pH (P)	Single Influence of Salinity (S)				Main Influence of pH (P)
	S1	S2	S3	S4	
	(LSD _{0.05} = 1.2700)				
P1	80.990 ^a	82.230 ^{ab}	83.767 ^{abc}	81.897 ^{ab}	82.226 ^a
P2	83.880 ^{ab}	84.377 ^{abc}	85.420 ^{cd}	84.857 ^{cd}	84.633 ^a
P3	82.940 ^{abc}	81.143 ^a	84.930 ^{cd}	84.813 ^{cd}	83.462 ^a
Main influence of Salinity (S) (LSD _{0.05} = 0.743)	82.390 ^a	83.856 ^{ab}	84.712 ^{abc}	82.660 ^{ab}	

431 The mechanism for removing nitrogen in water is determined by several factors, including bacterial activity (Giersberg
 432 et al., 1986), uptake by plants (Breen, 1990) and evaporation (Sanchez-Monodero et al., 2001). In Cyanobacteria, nitrogen
 433 is a macronutrient that plays an important role in the formation of biochemical compounds such as nucleic acids (DNA,
 434 RNA), amino acids (protein) and pigments (chlorophyll and phycoerythrin) (Markou et al., 2014). The results of the LSD
 435 on the main pH factor showed that the reduction in total nitrogen content in *Arthrospira* culture media in treatment P2
 436 was significantly higher than in treatments P1 and P3. This is due to the higher density of *Arthrospira* in treatment P2
 437 compared to other treatments, so that the utilization of nitrogen by *Arthrospira* in culture media is greater than others.
 438 Markou et al. (2014) showed that the higher density of *Arthrospira* could be higher the absorption of nutrients including
 439 nitrogen.

440 The value of reducing total nitrogen content in S3 treatment was significantly higher than for other treatments. This
 441 showed that treatment S3 caused *Arthrospira* to absorb nitrogen higher than other treatments in line with the high density
 442 and rendement of phycoerythrin *Arthrospira* obtained in this study. Jabben and Ahmad (2011) showed that salinity in
 443 culture media influences nitrogen absorption and protein biosynthesis. Reduction of total nitrogen content in *Arthrospira*
 444 culture media due to interactions between pH and salinity factors showed that treatment P2S3 was significantly higher than
 445 other treatments. With the optimal conditions (pH and salinity), *Arthrospira* is able to make maximum use of nitrogen.
 446 This can be seen from the highest density, growth rate and rendement of phycoerythrin found in treatment P2S3. The
 447 amount of nitrate and phosphate decreases with increasing growth of *Chlorella vulgaris* and *Arthrospira platensis* (Sayadi
 448 et al., 2016). This is because algae have the ability to absorb nutrients such as nitrogen and phosphate are use to carry out
 449 photosynthesis and protein production. Reduction of phosphorus content in waters is influenced by the process of
 450 absorption, complexation, deposition and assimilation (between microbials and plant biomass) (Tanner et al., 1999).
 451

452 **Table 5. Reduction of phosphate content in *Arthrospira* culture medium (%)**

Single Influence of pH (P)	Single Influence of Salinity (S)				Main Influence of pH (P)
	S1	S2	S3	S4	
P1	70.500	71.667	73.000	72.333	71.875
P2	74.667	74.000	74.667	72.667	74.000
P3	70.333	70.333	73.667	72.667	71.750
Main influence of Salinity (S)	71.833	72.000	73.778	72.556	

453 The results of LSD_{0.05} on the main factor of pH showed that each treatment did not significantly affect the reduction of
 454 phosphate content in *Arthrospira* culture medium. Plants can only absorb phosphorus in the form of H₂PO₄ and HPO₄²⁻
 455

457 free orthophosphate ions (Becquer et al., 2014). The orthophosphate content decreases with increasing media pH. Cercozi
 458 and Fitzsimmons (2016) showed the orthophosphate content increases in the pH range from 5.5 to 8.5 and decreases when
 459 pH 10. The fall in the orthophosphate content at pH 10 is due to an increase in calcium phosphate formation. The value of
 460 reducing the phosphate content in *Arthrospira* culture medium was presented in Table 5.

461 The salinity factor, administration of different salinity in each treatment has no significant effect on reducing the
 462 phosphate content. Bassin et al. (2011) explained the reduction of phosphorus will be inhibited when a combination of Cl⁻
 463 and nitrate and Cl⁻ concentration more than 2.5 g L⁻¹. The interaction effect of differences in pH and salinity, each
 464 treatment had no significant effect on reducing phosphate content. Hua-Sheng et al. (1995) showed that the utilization of
 465 Dissolved Organic Phosphorus (DOP) can be through active uptake into cells or by extracellular mineralization by
 466 phosphatase enzymes. However, most DOP compounds cannot be assimilated directly with microalgae because they have
 467 been mineralized. Markou et al. (2014) stated that phosphorus is a macronutrient that plays an important role in the
 468 preparation of nucleic acids (RNA and DNA), phospholipids and energy-carrying molecules (ATP). The phosphorus
 469 content in plants is lower than Ca, N, and K (Sasaki et al., 2018). Although the analysis of variance shows that the results
 470 are not significantly different, but the highest phosphate reduction still existed in treatment P2S3.

471 **Morphology of *Arthrospira* in various pH and salinity media**

472 Morphology of *Arthrospira* was affected by increasing or decreasing physical or chemical factors in their culture
 473 media. Salinity and acidity value combination at this study didn't change the filament of *Arthrospira* significantly as their
 474 filament of *Arthrospira* under microscope with 100x magnification (Figure 7). The morphological forms of *Arthrospira*
 475 were not different in all of pH and salinity treatments. The waste water catfish pond media could affected in the linearizing
 476 filament. This study indicated that salinity and acidity of culture media didn't effect on various form filament, either
 477 straight and helical.

478 The straight filaments were observed for *Arthrospira* strains during two years of cultivation, and their presence in
 479 *Arthrospira* sp. Nigrita C1 cultures was constant. The various morphological plasticity, greatly influenced by the growth
 480 stage and exogenous parameters, such as temperature and light intensity, was observed for *Arthrospira* strains
 481 (Papapanagiotou and Gkeldis, 2019). There are indications that adaptability to change in environmental conditions is
 482 relatively rapid and also subsequent changes at the genetic level can be realized quickly. This means that we can easily
 483 find different genotypes in various stable, ecologically different habitats. Morphologically similar strains were cultured for
 484 a long time under uniform and stable conditions (Komarek, 2016). But the morphological changes couldnot be effected by
 485 acidity and salinity of culture media.

Figure 7. Morphology of *Arthrospira* in catfish wastewater culture media at several treatment of pH and salinity
Figures 7 is not clear, should be redrawn for high quality.

Conclusions

Arthrospira that is cultured on waste media (observed in liquid culture) indicated some short and linear filaments. Identified *Arthrospira* had a genetic distance of 0.8% between AF and AW isolates. AF isolates had a close relationship with *Arthrospira platensis* petII species originating from Japan (bootstrap value of 95%) while AW isolates form phylogenetic branches which are separated from AF isolates and *Arthrospira platensis* petII species originating from Japan (bootstrap value 85%). The catfish culture wastewater media at different pH and salinity affects the density, growth rate and rendement of phycoerythrin *Arthrospira platensis*. The highest density, growth rate and rendement of phycoerythrin was in P2S3 treatment (pH 8.5 ± 0.2 and salinity of 20 ‰) which produced a maximum density of 0.867 g L⁻¹, growth rate of 22.020% day⁻¹ and the rendement of phycoerythrin of 11.334 %.

ACKNOWLEDGMENT

We thank staff at Aquaculture Laboratory and Plant Physiology Laboratory, Faculty of Agriculture, Sriwijaya University, Indonesia. The authors also acknowledge the contribution of the Sriwijaya University for Profession Research Grant (No. 01-44.25/UN9-SB3.LP2M-PT/2019).

Dear Smujo Editor,
We had corrected our manuscript based on the reviewer's suggestion. We are sorry, we couldn't redraw the figure 4 and 7, because we don't have a high-quality picture. We hope, the picture can be enough to display the morphotype differences of *Arthrospira* filaments.
Thank you for your help and suggestions.
Best regards
Marini Wijayanti

12 **Abstract.** *Arthrospira* production technology in catfish waste media can be an alternative to reduce environment
13 pollution. However, some environmental factors such as nutrition, light and water content can influence characterization of
14 *Arthrospira* at the genetic and physiologic level. *Arthrospira platensis* is one of the phycocyanin-producing cyanobacteria
15 and can be cultured using catfish culture wastewater. Water quality especially pH and salinity can effect of growth rate and
16 rendement of phycocyanin from *Arthrospira platensis*. This study aimed to identify the species and morphological forms of
17 *Arthrospira* cultured using technical fertilizer and waste media, as well as to know the phylogenetic trees between species
18 in this study and the GeneBank based on the 16S rRNA gene, and determine the optimum of pH and salinity required in
19 the medium of catfish culture wastewater to phycocyanin maximum production of *Arthrospira*. The optimization of pH and
20 salinity method used Completely Randomized Design (CRD) factorial with 2 factors consisting of the first factor with 3
21 treatments and the second factor with 4 treatments and 3 replications. The first factor was pH of culture medium i.e. pH
22 6.5 ± 0.2, pH 8.5 ± 0.2 and pH 10.5 ± 0.2. The second factor was salinity of culture medium, that were salinity 0 ppt (Ppt),
23 per thousand (‰), 10 ppt, 20 ppt and 30 ppt. Parameters observed in *Arthrospira* include density, growth rate, rendement
24 of phycocyanin, and decreased of total nitrogen and phosphate content in culture media. The results showed that
25 morphology *Arthrospira* cultured on technical fertilizer media (AF) had a longer and helix filament compared to
26 *Arthrospira* cultured on waste media (AW) which showed several linear and shorter filaments. Both samples have a
27 genetic distance of 0.068 (6.8%). Phylogenetic trees indicated that AF had a close relationship with *Arthrospira platensis*
28 peth from Japan (bootstrap value 95%). While AW formed a separate sub cluster of AF isolates and *Arthrospira platensis*
29 peth from Japan (bootstrap value of 85%). The best treatment in this study was P2S3 (pH 8.5 ± 0.2 with salinity 20 ppt),
30 which produced 0.807 grams maximum density, growth rate of 22.026 %day⁻¹ and 11.347 mg.g⁻¹ rendement of
31 phycocyanin.
32 **Keywords:** catfish culture wastewater, DNA barcode, pH, phycocyanin, phylogenetic analysis, salinity, *Spirulina* (Arthrospira) 16S
33 rRNA

34 **INTRODUCTION**
35 *Arthrospira* is a genus of cyanobacterial microalgae, commonly known under the taxonomically incorrect brand name
36 'Spirulina' (Papapanagiotou & Gkelis, 2019). The cyanobacterial genus *Arthrospira* (Sizemberger ex Gomont 1852)
37 contains at present 23 species, along with 12 infraspecific taxa (Guiry & Guiry, 2014; Guiry, 2012; [unpublished](#)). They have
38 variety characteristic of -molecular, morphology, and physiology that based on polyphasic approach. Various genotypes
39 are adaptable to various specialized ecosystems. The combination of different methods should be based on molecular
40 sequencing as the basic approach, to which must be added other criteria (morphological, ecological) if they are available
41 and which are distinct and recognizable in cyanobacterial populations (Kondrek, 2016). A polyphasic approach to include
42 all the criteria obtained from morphological, biochemical, molecular studies, and phylogenetic to understand
43 cyanobacterial classification as like as *Arthrospira* classification (Kondrek, 2018).
44 Recent studies have shown that *Arthrospira* can be used for treating wastewater, including effluent from fish culture,
45 because the biomass can metabolize the nutrients and remove the [ammonia](#) from aquaculture effluent efficiently
46 (Zhang et al., 2016; [unpublished](#)). Industrial and processing wastes and by-products for culturing *Spirulina* (*Arthrospira*) are
47 also being considered as alternative culture media, as like as aquaculture waste water (Ragaza et al. 2020). Wijayanti et al.
48 2018, Widyantoro et al., 2018). Aquaculture could apply an integrated strategy of simultaneously treating aquaculture
49 effluent while producing the biomass to supplement fish diets. The nutrient composition in their biomass depends on their
50 environmental factor for growing biomass. Their character could be different with the various media for growth.

51 Basically, *Arthrospira*'s morphology is characterized by trichomes that circular regularly (helical). However, abnormal
52 morphology can also occur in *Arthrospira* as a circular shape that is irregular even linear. In some cultivation conditions,
53 linear filaments can spontaneously return to the helix. However, there are significant differences in morphology,
54 ultrastructure, physiology, biochemistry, and genetic characteristics between the original filament and the linear filament
55 but not the difference between the original and the returned filament. Linearization in *Arthrospira* is a variation on the
56 genetic level that can be caused by several environmental factors such as nutrition, light and content of water media for
57 growth (Wang and Zhao 2005). According to Liu et al., (2016), DNA barcoding has developed as a reliable technology
58 for identifying species based on variations in the sequence of standard DNA regions. This method is used successfully in a
59 variety of biological applications including finding cryptic species, detecting invasive species, and identifying plants. DNA
60 barcoding is a simple short genome sequence amplified via PCR using appropriate primers (Adamowicz, 2015). DNA
61 barcoding using the 16S rRNA gene has been widely used to determine bacterial DNA characterization. Therefore,
62 identification of *Arthrospira* using the 16S rRNA gene needs to be done to get the characterization of *Arthrospira* that is
63 cultured on technical fertilizer and waste media and determine the phylogenetic tree structure that has been recorded in
64 GenBank.

65 Culture of *Arthrospira* (*Spirulina*) in *Clarias* pond farming wasted water could have specific characterization for
66 optimal pH value and salinity. Their adaptation to grow in organic waste water make change in bioactive and important
67 compound production. Their biomass has a nutritional value of 55-70% protein, 6-10% lipid, 20% carbohydrate, besides
68 being rich in minerals, vitamins, and pigments (Borowitzka et al., 2016; Verma et al., 2014). Some color pigments
69 that can be produced such as phycocyanin (blue pigment), allophycocyanin (blue-green) and phycoerythrin (red pigment)
70 (Sharma and Tiwari, 2011; Verma et al., 2015). Phycocyanin is pigment in *Arthrospira* which has functions as an
71 antioxidant (Prenantyo and Limanari, 2008), a source of food coloring, cosmetics, pharmaceuticals and drugs (Tang et
72 al., 2020; Tiwari, Tiwari, & Tiwari, 2020), anti-inflammatory, anti-oxidative and anticancer (Liu et al., 2013). One of the factors
73 that influence phycocyanin levels in biomass (Tanjajurrahmi et al., 2017). The pH and salinity of culture media can affect
74 the biomass of *Arthrospira* (Ciferri, 1983; Marek et al., 1987; Planes et al., 2002; Ismail et al. (2016) showed that the
75 diversity of the chemical composition of biomass is influenced by the pH of the growth media. Value of pH and
76 environmental factors, especially salinity, influence the productivity of cell biomass, photosynthesis, shape, and flow of
77 cellular metabolic activity that affect the dynamics of cell composition (Hu, 2004). The optimal pH value for growth of
78 *Arthrospira* sp is 7-10.5 (Hariyati, 2008), and salinity from 15-30 ‰ (Thajuddin and Subramanian, 2005). The salinity
79 and pH value of *Arthrospira* culture media have been known to affect the morphology of the filament.

80 The aims of this study is characterizing morphological forms and DNA barcode based on the 16S rRNA gene of
81 *Arthrospira* (*Spirulina*) cultured in fertilizer and waste water effluent of *Clarias* pond farming media, and determining
82 optimal pH value and salinity of culture media for growth and phycocyanin production, especially in *Clarias* pond farming
83 waste water media and morphological changes of their filament.

84 MATERIALS AND METHODS

85 *Arthrospira* cultured in agar media

86 Bacto agar was weighed as much as 2 g dissolved in 100 ml of water. The water used was swamp water and catfish
87 culture waste that has been filtered and sterilized using an autoclave. Sterilized swamp water was then added with 0.02
88 gram MgSO₄ fertilizer, CaCl₂ 0.004 gram, EDTA 0.008 gram, urea 0.03 gram, Zn (Sulfate of Ammonium) 0.132
89 grams, 0.4 gram baking soda, AB solution 1 ml (A solution: Calcium Nitrate 64.76%, Potassium Nitrate 33.66%, Fe
90 EDTA 2.08% (all components) 20 grams / 100 ml B solution: Potassium dihydrogenphosphate 24.83%, Ammonium sulfate
91 9.41%, Potassium sulfate 2.79%, Magnesium sulfate 66.91%, Cupric sulfate 0.03%, Zinc sulfate 0.12%, Boric acid
92 0.31%, Manganese sulfate 0.62%, Ammonium heptamolybdate 0.01% (all components) 20 grams/100 ml water) and
93 TSP (Triple Super Phosphate) 0.05 grams were then homogeneous using magnetic stirrers. Next, waste water
94 was sterilized by an autoclave then cooled. Bactoagar was added to the technical fertilizer and waste solution to be
95 homogenized using a magnetic stirrer and then boiled using a hot plate until all the ingredients dissolve and then autoclave
96 again. The agar media was made with a pH of 7 and a salinity of 10 ppt or 10 g L⁻¹ (Hidayati et al., 2019). (Where is the
97 reference?)

98 *Arthrospira* cultivated in liquid media was taken 100 µl using micropipette and spread to the surface of a petri dish
99 containing bactoagar media by using a sterilized spreader rod. Petri dishes were wrapped in wrapping plastic and then
100 given a lamp lighting (light intensity 2000-4000 lux) with a dark: light ratio = 0:24 hours. *Arthrospira* was observed every
101 day until it grows blue green. After growing, *Arthrospira* was re-cultured in agar media by the 4 quadrant scratch method.
102 The cultures were used as isolate samples for determining DNA barcodes. The biomass of *Arthrospira* was isolated from
103 commercial *Spirulina* TopSpira East Jakarta, Indonesia.

104 What the source of *Arthrospira*? The source of *Arthrospira* from TopSpira Spirulina East Jakarta.

105 Why not use a specific Zarrenk medium? Because the commercial *Spirulina* was cultured in technical fertilizer media
106 directly, and we used the media based on our previous study about technical media in laboratory scale. The result showed
107 that this technical media can substituted Zarrenk Medium for growing *Spirulina* biomass in more cheap medium than ZM.

108 DNA extraction

109 DNA extraction was carried out according to procedures in which there was a Presto TM Mini gDNA Bacteria Kit
110 (Geneaid Biotech Ltd.). DNA extraction consisted of several stages: sample preparation, lysis, purification, and
111 precipitation or washing. The sample used was 0.15 grams of wet weight for one extraction (Geneaid manual). (Where is
112 the reference?)

113 DNA amplification

114 The process of DNA amplification using the PCR (Polymerase Chain Reaction) method was performed using 2 µl
115 forward primers 63T (5'-CAGGCCC TAA CAC ATG CAA GTC-3') and reverse primer 138T (5'-GGG CGG WGT GTA
116 CAA GGC-3') (Marchesi et al., 1998). The total composition of the PCR mixture was 50 µl which consisted of 25 µl Go
117 Taq Green, 15 µl NPW (Nuclease Free Water) and 8 µl *Arthrospira* DNA extraction template. DNA amplification was
118 carried out in a thermocycler: the initiation cycle at 95°C for 5 minutes, followed by 30 denaturation cycles at 94°C for 30 seconds,
119 annealing at 55°C for 30 seconds, then the extension stage at 72°C for 1 minute, and the final stage 72°C for 7 minutes
120 (Lee et al., 2005).

121 Electrophoresis

122 Electrophoresis was carried out using 1% agarose gel at 75 V for 35 minutes. Agarose that have been electrophoretic
123 was immersed with a mixture of 10 µl diamond dye solution and 100 ml TAE 1x buffer solution for 30 minutes without
124 exposure to light. The results were visualized through gel documentation by observing DNA migration using a
125 transilluminator UV.

126 Gene Sequencing

127 *Arthrospira* DNA samples that were successfully amplified using PCR were then sequenced in the fragments of 16S
128 rRNA gene. The amplified products were sequenced through the services of the Macrogen Institute in Jakarta. The DNA
129 sequences obtained in the form of fasta format were aligned using MEGA 6.0 software and then uploaded through the
130 Basic Local Alignment Search Tool (BLAST) program. BLAST was a program to search for and analyze the homology of
131 an organism's sequence, on the ncbi.nlm.nih.gov website so that its homology can be identified with other genus
132 *Arthrospira* 16S rRNA gene sequences registered in the GenBank database. The genetic distance and phylogenetic trees
133 between genera were constructed using the Neighbor Joining (NJ) method. The phylogenetic tree was constructed through
134 the Mega 6.0 software application using the Neighbor-Joining (NJ) method of the Maximum Composite Likelihood model
135 and Substitutions to include d. Transitions + Transversions with 1000x bootstrap. Meanwhile *Arthrospira* morphologicals
136 form analysis were presented in the form of images and discussed descriptively by referring to the appropriate literature.

137 Optimization of pH and salinity for growing *Arthrospira* in Catfish farming wasted water

138 The experimental design for optimizing pH and salinity media for growing *Arthrospira* in Catfish farming wasted water
139 was a Factorial Completely Randomized Design (CRD) consisting of the first factor with 3 treatments and the second
140 factor with 4 treatments and 3 replications. The first factor was the difference of pH in culture media, including P1: culture
141 media pH 6.5 ± 0.2, P2: culture media pH 8.5 ± 0.2 and P3: culture media pH 10.5 ± 0.2. The second factor was the
142 difference of salinity in culture media i.e. S1: salinity of 0 ‰, S2: salinity of 10 ‰, S3: salinity of 20 ‰, and S4: salinity
143 of 30 ‰ (What is the type of salt? Coarse sea salt).

144 Culture preparation

145 The equipment used in this study was sterilized using 70% alcohol to minimize the contaminants that inhibit the
146 productivity of *Arthrospira*. The containers used plastic bottles with capacity of 5 L volume of 30 units. The plastic bottle
147 were sterilized using a potassium permanganate solution (2 mg L⁻¹). Catfish culture wastewater obtained from catfish
148 farming ponds measuring 2 m x 1 m, and high of water media was 20 cm (Figure 1). The density used in the pond
149 was 330 fish/400 L⁻¹ with 150 grams fish⁻¹, maintained for 2 months by providing artificial feed (protein 31%-33%), twice
150 per day at satiation. Catfish culture wastewater was previously sterilized by boiling in an autoclave and then cooled, while
151 the steril wastewater was treated with salinity. In treatments S1, S2, S3 and S4 were added with salt until salinity was
152 obtained according to the treatment. The wastewater media had a pH of 7.3, therefore there was an addition of HCl 1 N of
153 0.75 ml L⁻¹ in P1 treatment to reach a pH of 6.5. Meanwhile, in treatments P2 and P3, to get a pH of 8.5 and pH 10.5 there
154 was an addition of NaOH 8 N as much as 0.07 ml L⁻¹ and 0.45 ml L⁻¹.

Figure 1. Catfish farming pond

Figure 2. *Arthrospira* cultivation

Arthrospira cultivation.

Arthrospira previously used was cultured in catfish culture wastewater for culture stock with a density of 2 g L⁻¹. The stock was taken as much as 400 ml in 3000 ml of catfish culture wastewater in accordance with treatment. Aeration was used for agitation, the lighting using 50 watt TL lamps for 24 hours day⁻¹ during maintenance (Figure 2).

Harvest of biomass. [Wahar et al. the components of wastewater: total phosphorus 2.6 mg L⁻¹, total nitrogen 1.9 mg L⁻¹, total organic carbon 11.4 mg L⁻¹.](#)

Harvest of the biomass was after exponential phase by filtering. The biomass was dried using an oven for 14 hours at 40 °C. ([Adhiana-Hidayat et al., 2012](#) not found in the reference with modification). The dry biomass was used for the phycocyanin extraction process.

Phycocyanin extraction

The dry biomass was 0.04 g added by 1 ml of phosphate buffer pH 7, then homogenized and frozen in the freezer for 24 hours at a temperature of -4 °C. After 24 hours from the freezer, thawing process for 15 minutes. Samples were centrifuged for 30 minutes at 3000 rpm. After that, the sediment and the supernatant were separated. The resulting supernatant was phycocyanin which be analyzed using the Bennett and Bogorad method (1973).

The density of Arthrospira biomass.

Biomass density measurements were performed at each treatment and 3 replications every day at the same hour. The density of biomass was 1 ml of sample in each treatment with 3 replications. The 1 ml of sample into aluminum bowl. The sample and the aluminum bowl were weighed, then dried in the oven for 14 hours at 40 °C. The sample of water that had dried was weighed again. The dry biomass weight of *Arthrospira* biomass was converted to g L⁻¹.

Figure 3. Dry biomass of *Arthrospira platensis* after oven

The growth rate of *Arthrospira* can be calculated using the following formula according to Vonshak (1997):

$$\mu = \frac{\ln N_t - \ln N_0}{t} \times 100\%$$

Note : μ = daily growth rate (% day⁻¹)
t = time (days) from N₀ to N_t
N₀ = initial density (g L⁻¹)
N_t = density at the time t (g L⁻¹)

Measurement of total nitrogen and phosphate content in culture media was carried out at the beginning and the first day after the peak phase of each treatment.

The measurement of phycocyanin refers to Bennett and Bogorad (1973). The absorbed supernatant was measured using a spectrophotometer at wavelengths of 615 nm and 652 nm.

$$C\text{-phycocyanin (mg mL}^{-1}\text{)} = \frac{OD(615) \cdot 0.474 + OD(652)}{5.34}$$

$$\text{Rendement of phycocyanin (mg g}^{-1}\text{)} = \frac{C\text{-phycocyanin} \times V}{DB}$$

Rendement percentage of phycocyanin (%) = Rendement of phycocyanin (mg g⁻¹) x 100%

Note : C-phycocyanin = C-phycocyanin concentration (mg mL⁻¹)
V = Volume Volume (ml)
DB = Dry Biomass (0.04 g)
0.474 and 5.34 = coefficient of extinction (Bennett and Bogorad, 1973)

The results were submitted to simple analysis of variance tests (ANOVA) (p <0.05) and in the case of significant differences, the means were compared by the Least Significant Differences test (p<0.05).

RESULTS AND DISCUSSION

Morphology of Arthrospira

Arthrospira was cultivated using two different fertilizer media namely technical fertilizer and waste media. The morphology of commercial *Arthrospira* before fertilizer treatment was presented in Figure 4.

Note : a = helical form AF
b = helical form AW
c = straight form AW

Figure 4. Morphological identification results of *Arthrospira* isolate (CA = Commercial *Arthrospira*; AF= commercial *Arthrospira* cultured with technical fertilizer media; AW= commercial *Arthrospira* cultured with waste media) 40x magnification

The results of the identification of isolates showed that the isolate had a twisted filament shape resembling a spiral (helical). Based on Duviv's identification book (1955), it is known that the isolate used in the study was *Spirulina* (*Arthrospira*) *platensis*. *Arthrospira* is cyanobacteria belonging to the order Oscillatoriales which has a filament (trichome) that resembles a spiral (helical) but does not have heterocyst cells (Sze, 1998). Heterocyst cells are special thick-walled cells that play a role in nitrogen fixation from the air ([Bijay et al., 2020 not found in the reference Issa et al., 2014](#)). In this study *Arthrospira* cultured in different media had several linear/straight morphologies.

Based on Figure 2, *Arthrospira* which was cultured on technical fertilizer media has a longer and spiraling morphological form compared to another cultured on waste media. Their filaments have more linear morphological form, some spirals but not too long. According to Astiani et al (2016), *Arthrospira* growth is influenced by nutritional and environmental factors. Wang and Zhao (2005) explained that linearization that occurs in *Arthrospira* is a variation on the genetic level that can be caused by environmental factors such as lack of nutrition and high light intensity. In this study, isolates were cultured with the same light intensity of 2000-3000 lux with a light dark ratio of 9:24 hours. Linear filaments in AW have a lower metabolic rate compared to helical filaments. This is one of the adaptive mechanisms for *Arthrospira* to survive some environmental conditions that are not appropriate.

Phylogenetic Tree

The results of the 16S rRNA encoding gene sequences from AF and AW isolates were traced to other *Arthrospira* isolates present in GenBank through the BLAST program. The results of the BLAST analysis of *Arthrospira* samples cultivated in technical fertilizer and waste media with data in GenBank are presented in Table 1. Table 1 results of the BLAST analysis show the closeness between AF and AW isolates with other isolates in GenBank. It shows that *Arthrospira* technical fertilizer isolates and *Arthrospira* waste isolates have the closest homology to *Arthrospira platensis* peth1 species from Japan with percentage values respectively 100% and 94.3%.

Figure 5. Phylogenetic analysis with 1600 bootstrap AW (*Arthrospira* cultured in waste water media) and AF (*Arthrospira* cultured in fertilizer media)

Genetic distance was used to see kinship relationships from *Arthrospira* both AF and AW samples with sequential data from GenBank. AF isolate indicated a genetic distance of 0.068 with AW isolates. AW and AF isolates showed the lowest genetic distance respectively 0.089 and 0.060 with *Arthrospira platensis* peth1 from Japan. Analysis based on genetic distance showed that both isolates were belong to the same species namely *Spirulina platensis*, however the genetic distance was 0.068 (6.8%) meaning that there are intraspecies variations in the sample caused by mutations.

Phylogenetic tree *Arthrospira* isolates from technical fertilizer and waste media were presented in Figure 5. The phylogenetic tree is a two-dimensional graph showing relationships between organisms or population classifications based on their evolutionary history. The result of phylogenetic tree construction showed that both samples formed branches with a cluster. Phylogenetic tree from AF and AW isolate sequences formed cluster was separate with several other *Arthrospira* species from GenBank data.

The AF isolates had a close relationship with *Arthrospira platensis* peth1 species from Japan with a bootstrap value of 95%. Hadiani (2003) states that bootstrap analysis is performed to determine the level of confidence in grouping. Bootstrap value is considered high because according to Hall (2001), a clade can be trusted with a bootstrap value of 90%. In addition, Hillis and Bull (1993) state that bootstrap analysis with values of 70% or higher indicate a reliable grouping. The AW isolates formed a separate branch of AF isolates and *Arthrospira platensis* peth1 species. Genetically, they had diverse, and adapted to environmental conditions. The AW isolate indicated different strain from AF isolate groups. Ballot et al. (2004) stated that *Spirulina* from the same species and cultured under different conditions can form a separate subcluster with a bootstrap value of 79%. Zhao et al. (2006) identified and analyzed the number of restriction-modification genes in the cyanobacterial genome, seeing that more restriction-modification genes were found in cyanobacterial filaments (*Anabaena*, *Spirulina* and *Nostoc*) than dispenses (*Synechocystis*, *Synechococcus* and *Prochlorococcus*) this was due to the organism adapting to various environmental conditions, or the many variations in sources of nutrients that cause mutations.

Density and Growth Rate of *Arthrospira* cultured in wastewater of catfish farming

The biomass of *Arthrospira* displayed mechanism of adaptation in culture media. The wastewater media could make different characteristic of growth as like as filament. The maximum densities of *Arthrospira* cultured in wasted water were achieved on a different day. The daily density of *Arthrospira* during culture can be seen in Figure 6.

Figure 6. Cell density (dry weight with a moisture content of 1.2%) of *Arthrospira* in catfish rearing pond waste water

The graph presented in Figure 6, it show that in the culture period from day 1 to day 2, *Arthrospira* in each treatment experienced slow growth, because the cells were still adapting to their new environment. The exponential phase for the treatment of P2S2, P2S3, and P3S3 last from day 1 to day 8 of the culture period. In the treatment of P2S1, P2S4, P3S1 and P3S2 take place from 2nd until 8th day of the culture period. While the treatment of P1S1, P1S2, P1S3, P1S4, and P3S4 lasted from 3rd - 8th day of the culture period. The decreasing *Arthrospira* density for the treatment occurred from the day 9 to the day 11 of the culture. Lesmana et al. (2019) explained that the adaptation phase lasts from day 0 to day 1, while the exponential phase occurs from day 1 to day 7, and experiences a stationary phase from day 7 to day 9 then enters the death phase after the 7th day and 9th day. The decrease of density could be because of reducing the nutrients in the culture media. Soni et al. (2019), the concentration of nutrients in the media decreased after reaching the peak period. This is due to the higher density of *Arthrospira* in the culture media.

The maximum density of *Arthrospira* could be achieved on different day, between 5 - 8 days after culturing. The mean of maximum density could be 0.433-0.867 g L⁻¹ of dry biomass which cultured in catfish rearing waste water. The maximum cellular density of *A. platensis* which cultured in Nile fish rearing waste water, resulted in the production of 0.22 g L⁻¹ of dry biomass and maximum productivity of 0.03 g L⁻¹ day⁻¹ (Nogueira et al., 2018). The catfish rearing pond waste water has high potential as cultivation media for *Arthrospira* production.

The analysis of variance showed that differences in pH, salinity and interaction between factors (pH and salinity) significantly affect the maximum density and growth rate of *Arthrospira platensis*. The results of the LSD_{0.05} maximum density test and growth rate sequentially were presented in Table 1 and Table 2. LSD_{0.05} test results on the main factors of differences in pH, density and growth rate of *Arthrospira platensis* in the P2 treatment (pH 8.5 ± 0.2) were significantly higher than those in the P1 (pH 6.5 ± 0.2) and P3 treatments (pH 10.5 ± 0.2). According to Ismael (2016), the highest biomass of *Arthrospira platensis* is produced in media with a pH of 8.5-9.5. Although *Arthrospira platensis* can tolerate a wide pH range, a pH range farther from its optimal pH can reduce its growth rate. A low growth rate will also cause low biomass production.

Furthermore, the different salinity treatment factors showed that the maximum density and growth rate in treatment S3 (salinity of 20 ‰) were significantly higher compared to S1 (salinity of 0 ‰), S2 (salinity of 10 ‰) and S4 (salinity of 30 ‰) treatments. The S1 and S4 treatments were not significantly different and were the treatments that produced the lowest density compared to other treatments. Table 1 and Table 2 showed that the highest density and daily growth rate was found in the S3 (salinity of 20 ‰) treatment. This is supported by the results of Krougardi et al. (2015), that *Arthrospira platensis* cultured on Conway media was able to produce the highest density of 912.07 mL⁻¹ cells at a salinity of 20 ‰. While the density and growth rate between S1 and S4 treatments showed no significant difference. This is because the salinity of 0-30 ‰ is still within the range of salinity that can be tolerated by *Arthrospira*. Ughy et al. (2015) said that *Arthrospira platensis* is one of the species of *Cyanobacteria* that can grow in an euryhaline environment.

Table 1. Maximum density of *Arthrospira platensis* (g L⁻¹)

Single Influence of pH (P)	Single Influence of Salinity (S)				Main influence of pH (P) (LSD _{0.05} =0.053)
	S1 (0 ‰)	S2 (10 ‰)	S3 (20 ‰)	S4 (30 ‰)	
P1 (pH 6.5)	0.433 ^a	0.633 ^a	0.767 ^{ab}	0.467 ^a	0.575 ^a

Main Influence of Salinity (S) (LSD _{0.05} = 1.861)	17.566 ^a	19.585 ^a	20.614 ^a	16.829 ^a	

368 In Table 1 and 2

369 Salinity 10-20 and 30‰ means 100-700 and 50 gram per liter is very high and this under stress which means reduce of

370 growth rate.

371 How is this given growth rate?

372 The mean that get obtained, it is not correct (%/day), so, they are still range of salinity between fresh water (0 ppt),

373 brackish water (5-20 ppt) and sea water (more than 25 ppt). The various salinity used in the study still supports the growth

374 of *Arthrospira*.

375

376 The interaction between pH and salinity factors showed that the density and growth rate in treatment P2S3 (pH 8.5 ±

377 0.2 and salinity of 20 ‰) were significantly higher compared to other treatments. At maximum density, treatment P2S3

378 was not significantly different from treatments such as P1S3, P2S1, P2S2, P2S4, and P3S3. While in the growth rate,

379 treatment P2S3 was not significantly different from P1S3, P2S2, P2S4, P3S2 and treatments P3S3. Table 1 and Table 2

380 show that treatment P2 (pH 8.5 ± 0.2) is more dominant causing higher density and growth rate of *Arthrospira platensis*

381 despite being in different salinity ranges. As for the treatments P1 (pH 6.5 ± 0.2) and P3 (pH 10.5 ± 0.2) provide the

382 highest density when combined by the treatment S3 (salinity 20 ppt). The treatment of P1, P2, and P3 (pH 6.5 ± 0.2, 8.5 ±

383 0.2, and 10.5 ± 0.2) and S1, S2, S3 and S4 treatments (salinity of 0 ‰, 10 ‰, 20 ‰, and 30 ‰) still support the growth of

384 *Arthrospira platensis* with the best treatment found in the combined treatment P2S3 (pH 8.5 ± 0.2 with salinity of 20 ‰).

385 Mismatch of pH will cause lysis and can change the stage of pigment growth (Hariyani, 2008). The process of

386 photosynthesis affects the pH value. In daylight, aquatic plants release carbon dioxide from water for use in

387 photosynthesis. The release of carbon dioxide by plants occurs through respiration. When carbon dioxide is released,

388 carbonate builds up and hydrolyzed so that the pH of the water will increase (Boyd, 1990). Prasadi (2018) showed that

389 growth of *Arthrospira* could be inhibited if it was in the pH range above 10.5 or less than 7. Salinity is one of the factors

390 that can influence osmotic pressure for *Arthrospira* as like as others of microalgae. Pital and Lele (2005) microalgae can

391 experience cell shrinkage in conditions outside the cell salinity higher than inside the cell (hypertonic), and vice versa

392 under conditions of low salinity outside the cell (hypotonic) cell swelling will occur due to water molecules outside moves

393 into the cell. This condition affects the process of photosynthesis, and makes microalgae to produce secondary metabolites

394 in the form of β-carotene to sustain life against changes in salinity in culture media. While in isotonic conditions, cell fluid

395 is isotonic to its external media which causes low active ion transport and osmoefector exchange, making the Na-K-

396 ATPase enzyme activity at a maximum level and more energy will be utilized for growth (Rahmawati et al., 2012).

397 The optimal combination of pH and salinity causes the growth of *Arthrospira* to be maximal. The optimal salinity range for

398 *Arthrospira* is between 15-20 ‰, from the related research showed that the results of *Arthrospira* culture with 20 ‰ of

399 media salinity, pH 7.5-8.5 using fertilizer media (0.010 g L⁻¹ TSP, 0.030 g L⁻¹ Urza, and 0.030 g L⁻¹ ZA) and a culture

400 periode of 9 days produced a dry weight of *Arthrospira* of 0.0375 g L⁻¹ (Prasadi, 2018).

401

402 Remendement of phycoerythrin

403 The remendement of *Arthrospira* was presented in Table 3. The pH condition of maintenance media can be affect of

404 protein content in *Arthrospira* cells. The results of LSD_{0.05} on the main factor of pH showed that the remendement of

405 phycoerythrin in *Arthrospira* in treatment P2 was significantly higher compared to other treatments. Taufiqurrahmi et al.

406 (2017), the amount of *Arthrospira* biomass influences the high content of phycoerythrin. Table1 showed that the highest

407 *Arthrospira* biomass was found in treatment P2. It showed that the highest *Arthrospira* biomass produced the highest

408 remendement of phycoerythrin (Table 3). The culture medium of *Arthrospira* pH of 8.5 produced the highest C-phycoerythrin

409 content (Issaoui et al., 2010). Rahmawati et al. (2017) said that the higher of C-phycoerythrin followed the higher of

410 remendement of phycoerythrin.

411 LSD_{0.05} showed that the main factor of salinity showed the remendement of phycoerythrin in treatment S3 (salinity of 20

412 ‰) was significantly higher than other treatments. It is thought that the difference in salinity treatment has an impact on

413 the external osmotic pressure of *Arthrospira* cells which results in changes in cell composition especially phycoerythrin.

414 Sodium will flow into the cell and cause the release of phycoeritrin, phycoerythrin and allophycoerythrin from

415 PS II (Photosystem II) and stop the electron transporting to PS I (Photosystem I) followed by activation of the protective

416 mechanism. *Arthrospira* will produce carbohydrates to balance intracellular osmotic pressure and require more energy to

417 remove sodium ions from cells. In this case it will produce ammonium assimilation causes inhibition of protein synthesis

418 (Zhou et al., 2017).

419

Table 3. Phycoerythrin (%) yield in *Arthrospira* dry biomass at 8 days after inoculation

Single Influence of pH (P)	Single Influence of Salinity (S)				Main Influence of pH (P)
	(LSD _{0.05} = 0.194)				
	S1	S2	S3	S4	(LSD _{0.05} = 0.096)
P1	7.881 ^a	8.783 ^a	9.441 ^{ab}	8.187 ^a	8.623 ^a
P2	9.657 ^a	10.906 ^{ab}	11.347 ^{ab}	10.423 ^a	10.583 ^a
P3	8.970 ^a	9.408 ^a	10.134 ^{ab}	9.262 ^a	9.444 ^a
Main Influence of Salinity (S) (LSD _{0.05} = 0.111)	8.836 ^a	9.699 ^a	10.367 ^a	9.357 ^a	

421

422 The environment includes the availability of nutrients, pH, salinity, light and temperature can affect the growth and

423 accumulation of biopigments from microalgae (Sharma and Tiwari, 2014). The condition of culture media is able to

424 influence the growth phase of *Arthrospira*, causing changes in the composition and proportion of phycoeritrin,

425 phycoerythrin and allophycoerythrin (Simeunovic et al., 2013). The results of the LSD_{0.05} was showed that the remendement

426 of phycoerythrin *Arthrospira* on the interaction between factors in treatment P2S3 was significantly higher than in other

427 treatments, but it was not significantly different from treatment P2S2. This showed from the density and growth rate of

428 *Arthrospira*. The increasing salinity will cause maintenance media to be hypertonic towards cells and result in poor

429 absorption of nutrients by cells. These cells could reduce in protein and increase in carbohydrates from *Arthrospira* cells

430 (Ravelonandro et al., 2011).

431 Production of phycoerythrin was able to reach 12.4 % - 17.6% of biomass dry weight of *Arthrospira* cultured in Zarrook

432 Medium (ZM) (Prates et al., 2018; Garcia-Lopez et al., 2020). There are several factors that affect the remendement of

433 phycoerythrin include temperature, extraction time, mixing rate, biomass, type of solvent and the ratio of biomass to the

434 solvent (Taufiqurrahmi et al., 2016). The content of phycoerythrin in cyanobacteria increases when grown in low light

435 intensity. Phycoerythrin is a pigment associated with protein, polar and water soluble. The protein content of microalgae

436 are influenced by environmental conditions such as temperature, age of culture, light intensity, pH, salinity, and nutrient

437 limits (especially nitrogen). Nitrogen is an essential element needed for the synthesis of accessory pigments and

438 chlorophyll. When microalgae are growing fast, it requires large amounts of nitrogen and could consume phycoerythrin as

439 an alternative source of nitrogen for the production of biomass (Hsieh-Lo et al., 2019). It must be optimized for biomass

440 production and phycoerythrin content. The higher concentration of phycoerythrin will be followed by the remendement of

441 phycoerythrin. In this study, the phycoerythrin content is lower than previous study, because of different media for culturing

442 *Arthrospira*. The nutrient from ZM (pro analysis substances) is more complete for growing and forming phycoerythrin than

443 waste water catfish pond media, especially the trace mineral in ZM.

465 amount of nitrate and phosphate decreases with increasing growth of *Chlorella vulgaris* and *Arthrospira platensis* (Sayadi
 466 et al., 2016). This is because algae have the ability to absorb nutrients such as nitrogen and phosphate are use to carry out
 467 photosynthesis and protein production. Reduction of phosphorus content in waters is influenced by the process of
 468 absorption, complexation, deposition and assimilation (between microbes and plant biomass) (Tanner et al., 1999).

470 **Table 5. Reduction of phosphate content in *Arthrospira* culture medium (%)**

Single influence of pH (P)	Single Influence of Salinity (%)				Main influence of pH (P)
	S1	S2	S3	S4	
P1	70,500	71,667	73,000	72,333	71,875
P2	74,667	74,000	74,667	72,667	74,000
P3	70,333	70,333	73,667	72,667	71,750
Main influence of Salinity (S)	71,833	72,000	73,778	72,556	

471 The results of LSD _{0.05} on the main factor of pH showed that each treatment did not significantly affect the reduction of
 472 phosphate content in *Arthrospira* culture medium. Plants can only absorb phosphorus in the form of H₂PO₄ and HPO₄²⁻
 473 free orthophosphate ions (Bequer et al., 2014). The orthophosphate content decreases with increasing media pH. Cerco
 474 and Fitzsimmons (2016) showed the orthophosphate content increases in the pH range from 5.5 to 8.5 and decreases when
 475 pH 10. The fall in the orthophosphate content at pH 10 is due to an increase in calcium phosphate formation. The value of
 476 reducing the phosphate content in *Arthrospira* culture medium was presented in Table 5.

477 The salinity factor, administration of different salinity in each treatment has no significant effect on reducing the
 478 phosphate content. Bassin et al. (2011) explained the reduction of phosphorus will be inhibited when a combination of Cl⁻
 479 and nitrite and Cl⁻ concentration more than 2.5 g L⁻¹. The interaction effect of differences in pH and salinity, each
 480 treatment had no significant effect on reducing phosphate content. Hua-Sheng et al. (1995) showed that the utilization of
 481 Dissolved Organic Phosphorus (DOP) can be through active uptake into cells or by extracellular mineralization by
 482 phosphatase enzymes. However, most DOP compounds cannot be assimilated directly with microalgae because they have
 483 been mineralized. Markou et al. (2014) stated that phosphorus is a macronutrient that plays an important role in the
 484 preparation of nucleic acids (RNA and DNA), phospholipids and energy-carrying molecules (ATP). The phosphorus
 485 content in plants is lower than Ca, N, and K (Sasaqi et al., 2018). Although the analysis of variance shows that the results
 486 are not significantly different, but the highest phosphate reduction still existed in treatment P2S3.

488 **Morphology of *Arthrospira* in various pH and salinity media**
 489 Morphology of *Arthrospira* was affected by increasing or decreasing physical or chemical factors in their culture
 490 media. Salinity and acidity value combination at this study didn't change the filament of *Arthrospira* significantly as their
 491 filament of *Arthrospira* under microscope with 100x magnification (Figure 7). The morphological form of *Arthrospira*
 492 were not different in all of pH and salinity treatments. The waste water, catfish pond media could affected in the linearizing
 493 filament. This study indicated that salinity and acidity of culture media didn't effect on various form filaments, either
 494 straight and helical.
 495 The straight filaments were observed for *Arthrospira* strains during two years of cultivation, and their presence in
 496 *Arthrospira* sp. Nigrita C1 cultures was constant. The various morphological plasticity, greatly influenced by the growth
 497 stage and exogenous parameters, such as temperature and light intensity, was observed for *Arthrospira* strains
 498 (Papapanagiotou and Gkelis, 2019). There are indications that adaptability to change in environmental conditions is
 499 relatively rapid and also subsequent changes at the genetic level can be realized quickly. This means that we can easily
 500 find different genotypes in various stable, ecologically different habitats. Morphologically similar strains were cultured for
 501 a long time under uniform and stable conditions (Komarek, 2016). But the morphological changes couldnot be effected by
 502 acidity and salinity of culture media.

 534 ***Arthrospira* linearizing filament, morphological.**

535 **Conclusions**
 536 *Arthrospira* that is cultured on waste media (observed in liquid culture) indicated some short and linear filaments.
 537 Identified *Arthrospira* had a genetic distance of 6.8% between AF and AW isolates. AF isolates had a close relationship
 538 with *Arthrospira platensis* peth1 species originating from Japan (bootstrap value of 95%) while AW isolates form
 539 phylogenetic branches which are separated from AF isolates and *Arthrospira platensis* peth1 species originating from Japan
 540 (bootstrap value 85%). The catfish culture wastewater media at different pH and salinity affects the density, growth rate
 541 and rendement of phycoerythrin *Arthrospira platensis*. The highest density, growth rate and rendement of phycoerythrin was
 542 in P2S3 treatment (pH 8.5 ± 0.2 and salinity of 20 ‰) which produced a maximum density of 0.867 g L⁻¹, growth rate of
 543 22.020% day⁻¹ and the rendement of phycoerythrin of 11.334 %.

Manuscript received: 1 November 2020. Revision accepted: xxx November 2020.

Abstract. Wijayanti M, Syaifudin M, Yulisman, Nurianti Y, Hidayani A, Gofar N. 2020. Characterization of *Arthrospira platensis* cultured in waste water of *Clarias* catfish farming media: DNA barcode, helical form, growth, and phycocyanin. *Biodiversitas* 21: xxx. *Arthrospira* production technology in catfish waste media can be an alternative to reduce environmental pollution. However, some environmental factors such as nutrition, light and water content can influence characterization of *Arthrospira* at the genetic and physiologic level. *Arthrospira platensis* is one of the phycocyanin-producing cyanobacteria and can be cultured using catfish culture wastewater. Water quality especially pH and salinity can effect of growth rate and rendement of phycocyanin from *Arthrospira platensis*. This study aimed to identify the species and morphological forms of *Arthrospira* cultured using technical fertilizer and waste media, as well as to know the phylogenetic trees between species in this study and the GeneBank based on the 16S rRNA gene, and determine the optimum of pH and salinity required in the medium of catfish culture wastewater to phycocyanin maximum production of *Arthrospira*. The optimization of pH and salinity method used Completely Randomized Design (CRD) factorial with 2 factors consisting of the first factor with 3 treatments and the second factor with 4 treatments and 3 replications. The first factor was pH of culture medium i.e. pH 6.5 ± 0.2, pH 8.5 ± 0.2 and pH 10.5 ± 0.2. The second factor was salinity of culture medium, that were salinity 0 ppt (Parts per thousand/‰), 10 ppt, 20 ppt and 30 ppt. Parameters observed in *Arthrospira* include density, growth rate, rendement of phycocyanin, and decreased of total nitrogen and phosphate content in culture media. The results showed that morphology *Arthrospira* cultured on technical fertilizer media (AF) had a longer and helix filament compared to *Arthrospira* cultured on waste media (AW) which showed several linear and shorter filaments. Both samples have a genetic distance of 0.068 (6.8%). Phylogenetic trees indicated that AF had a close relationship with *Arthrospira platensis* petH from Japan (bootstrap value 95%). While AW formed a separate sub cluster of AF isolates and *Arthrospira platensis* petH from Japan (bootstrap value of 85%). The best treatment in this study was P2S3 (pH 8.5 ± 0.2 with salinity 20 ppt), which produced 0.867 grams maximum density, growth rate of 22.026 %·day⁻¹ and 11.347 mg·g⁻¹ rendement of phycocyanin.

Keywords: catfish culture wastewater, DNA barcode, pH, phycocyanin, phylogenetic analysis, salinity, *Spirulina*(*Arthrospira*), 16S rRNA

INTRODUCTION

Arthrospira is a genus of cyanobacterial microalgae, commonly known under the taxonomically incorrect brand name 'Spirulina' (Papapanagiotou & Gkelis, 2019). The cyanobacterial genus *Arthrospira* Stizenberger ex Gomont 1892 contains at present 23 species, along with 12 infraspecific taxa (Guiry & Guiry, 2010). They have variety characteristic of molecular, morphology, and physiology that based on polyphasic approach. Various genotypes are adaptable to various specialized ecosystems. The combination of different methods should be based on molecular sequencing as the basic approach, to which must be added other criteria (morphological, ecological) if they are available and which are distinct and recognizable in cyanobacterial populations (Komarek, 2016). A polyphasic approach to include all the criteria obtained from morphological, biochemical, molecular studies, and

phylogenetic to understand cyanobacterial classification as like as *Arthrospira* classification (Komárek, 2018).

Recent studies have shown that *Arthrospira* can be used for treating wastewater, including effluent from fish culture, because the biomass can metabolize the nutrients and remove the pollutant from aquaculture effluent efficiently (Zhang et al., 2019). Industrial and processing wastes and by-products for culturing *Spirulina* (*Arthrospira*) are also being considered as alternative culture media, as like as aquaculture waste water (Ragaza et al. 2020, Wijayanti et al. 2018, Widyantoro et al., 2018). Aquaculture could apply an integrated strategy of simultaneously treating aquaculture effluent while producing the biomass to supplement fish diets. The nutrient composition in their biomass depends on their environmental factor for growing biomass. Their character could be different with the various media for growth.

Basically, *Arthrospira*'s morphology is characterized by trichomes that circular regularly (helical). However, abnormal morphology can also occur in *Arthrospira* as a circular shape that is irregular even linear. In some cultivation conditions, linear filaments can spontaneously return to the helix. However, there are significant differences in morphology, ultrastructure, physiology, biochemistry, and genetic characteristics between the original filament and the linear filament but not the difference between the original and the returned filament. Linearization in *Arthrospira* is a variation on the genetic level that can be caused by several environmental factors such as nutrition, light and content of water media for growth (Wang and Zhao 2005). According to Liu et al., (2016), DNA barcoding has developed as a reliable technology for identifying species based on variations in the sequence of standard DNA regions. This method is used successfully in a variety of biological applications including finding cryptic species, detecting invasive species, and identifying plants. DNA barcoding is a simple short genome sequence amplified via PCR using appropriate primers (Adamowicz, 2015). DNA barcoding using the 16S rRNA gene has been widely used to determine bacterial DNA characterization. Therefore, identification of *Arthrospira* using the 16S rRNA gene needs to be done to get the characterization of *Arthrospira* that is cultured on technical fertilizer and waste media and determine the phylogenetic tree structure that has been recorded in GeneBank.

Culture of *Arthrospira* (*Spirulina*) in *Clarias* pond farming wasted water could have specific characterization for optimal pH value and salinity. Their adaptation to grow in organic waste water makes change in bioactive and important compound production. Their biomass has a nutritional value of 55-70% protein, 6-10% lipid, 20% carbohydrate, besides being rich in minerals, vitamins, and pigments (Borowitzka et al., 2016; Vernes et al., 2015). Some color pigments that can be produced such as phycocyanin (blue pigment), allophycocyanin (blue-green) and phycoerythrin (red pigment) (Sharma and Tiwari, 2011; Vernes et al., 2015). Phycocyanin is pigment in *Arthrospira* which has functions as an antioxidant (Pirenantyo and Limantara, 2008), a source of food coloring, cosmetics, pharmaceuticals and drugs (Tang et al., 2020; Tiwari & Tiwari, 2020), anti-inflammatory, anti-oxidative and anticancer (Liu et al., 2013). One of the factors that influence phycocyanin levels is biomass (Taufiqurrahmi et al., 2017). The pH and salinity of culture media can affect the biomass of *Arthrospira* (Ciferri, 1983; Marek et al., 1987; Planes et al., 2002). Ismaiel et al. (2016) showed that the diversity of the chemical composition of biomass is influenced by the pH of the growth media. Value of pH and environmental factors, especially salinity, influence the productivity of cell biomass, photosynthesis, shape, and flow of cellular metabolic activity that affect the dynamics of cell composition (Hu, 2004). The optimal pH value for growth of *Arthrospira* sp is 7-10.5 (Hariyati, 2008), and salinity from 15-30 ‰ (Thajuddin and Subramanian, 2005). The

salinity and pH value of *Arthrospira* culture media have been known to affect the morphology of the filament.

The aims of this study is characterizing morphological forms and DNA barcode based on the 16S rRNA gene of *Arthrospira* (*Spirulina*) cultured in fertilizer and waste water effluent of *Clarias* pond farming media, and determining optimal pH value and salinity of culture media for growth and phycocyanin production, especially in *Clarias* pond farming waste water media and morphological changes of their filament.

MATERIALS AND METHODS

Arthrospira cultured in agar media

Bacto agar was weighed as much as 2 g dissolved in 100 ml of water. The water used was swamp water and catfish culture waste that has been filtered and sterilized using an autoclave. Sterilized swamp water was then added with 0.02 gram $MgSO_4$ fertilizer; $CaCl_2$ 0.004 gram; EDTA 0.008 gram; urea 0.03 gram; ZA (Sulphate of Ammonia) 0.132 grams; 0.4 gram baking soda; AB solution 1 ml mix A solution (Calcium Nitrate 64,26%, Potassium Nitrate 33,66%, Fe EDTA 2,08%) 2 grams / 10 ml and B solution (Potassium dihydrophosphate 25,83%, Ammonium sulfate 9,41%, Potassium sulfate 2,78%, Magnesium sulfate 60,91%, Cupric sulfate 0,03%, Zinc sulfate 0,12%, Boric acid 0,31%, Manganese sulfate 0,62%, Ammonium heptamolybdate 0,01%) 2 grams/10 ml water and TSP (Triple Super Phosphate) 0.05 grams were then homogeneous using magnetic stirrers. Next, wasted water was sterilized by an autoclave then cooled. Bactoagar was added to the technical fertilizer and waste solution to be homogenized using a magnetic stirrer and then boiled using a hot plate until all the ingredients dissolve and then autoclave again. The agar media was made with a pH of 7 and a salinity of 10 ppt or 10 g.L^{-1} (Hidayani et al, 2019).

Arthrospira cultivated in liquid media was taken 100 μl using micropipette and spread to the surface of a petri dish containing bactoagar media by using a sterilized spreader rod. Petri dishes were wrapped in wrapping plastic and then given a lamp lighting (light intensity 2000-4000 lux) with a dark: light ratio = 0:24 hours. *Arthrospira* was observed every day until it grows blue green. After growing, *Arthrospira* was re-cultured in agar media by the 4 quadrant scratch method. The cultures were used as isolate samples for determining DNA barcodes. The biomass of *Arthrospira* was isolated from commercial *Spirulina* TopSpira East Jakarta, Indonesia.

The commercial *Arthrospira* was cultured in technical fertilizer media directly, and we used the media based on our previous study about fertilizer media in laboratory scale (Laboratorium of Aquaculture, Faculty of Agriculture, Sriwijaya University). The result showed that this fertilizer media can substitute Zarrouk Medium (ZM) for growing *Spirulina* biomass in cheaper medium than ZM (Wijayanti et al, 2018).

DNA extraction

DNA extraction was carried out according to procedures in which there was a Presto™ Mini gDNA Bacteria Kit (Geneaid Biotech Ltd.). DNA extraction consisted of several stages: sample preparation, lysis, purification, and precipitation or washing. The sample used was 0.15 grams of wet weight for one extraction (Geneaid manual).

DNA amplification

The process of DNA amplification using the PCR (Polymerase Chain Reaction) method was performed using 2 µl forward primers 63f (5'-CAGGCC TAA CAC ATG CAA GTC-3') and reverse primer 1387r (5'-GGG CGG WGT GTA CAA GGC-3') (Marchesi et al., 1998). The total composition of the PCR mixture was 50 µl which consisted of 25 µl Go Taq Green, 13 µl NFW (Nuclease Free Water) and 8 µl *Arthrospira* DNA extraction template. DNA amplification was carried out in stages: the initiation cycle at 95°C for 5 minutes, followed by 30 denaturation cycles at 94 °C for 30 seconds, annealing at 55 °C for 30 seconds, then the extension stage at 72 °C for 1 minute, and the final stage 72 °C for 7 minutes (Lee et al., 2003).

Electrophoresis

Electrophoresis was carried out using 1% agarose gel at 75 V for 35 minutes. Agarose that have been electrophoretic was immersed with a mixture of 10 µl diamond dye solution and 100 ml TAE 1x buffer solution for 30 minutes without exposure to light. The results were visualized through gel documentation by observing DNA migration using a transilluminator UV.

Gene Sequencing

Arthrospira DNA samples that were successfully amplified using PCR were then sequenced in the fragments of 16S rRNA gene. The amplified products were sequenced through the services of the Macrogen Institute in Jakarta. The DNA sequences obtained in the form of fasta format were aligned using MEGA 6.0 software and then uploaded through the Basic Local Alignment Search Tool (BLAST) program. BLAST was a program to search for and analyze the homology of an organism's sequence, on the ncbi.nlm.nih.gov website so that its homology can be identified with other genus *Arthrospira* 16S rRNA gene sequences registered in the GenBank database. The genetic distance and phylogenetic trees between genera were constructed using the Neighbor Joining (NJ) method. The phylogenetic tree was constructed through the Mega 6.0 software application using the Neighbor-Joining (NJ) method of the Maximum Composite Likelihood model and Substitutions to include d: Transitions + Transversions with 1000x bootstrap. Meanwhile *Arthrospira* morphologicals form analysis were presented in the form of images and discussed descriptively by referring to the appropriate literature.

Optimization of pH and salinity for growing *Arthrospira* in Catfish farming wasted water

The experimental design for optimizing pH and salinity media for growing *Arthrospira* in Catfish farming wasted

water was a Factorial Completely Randomized Design (CRD) consisting of the first factor with 3 treatments and the second factor with 4 treatments and 3 replications. The first factor was the difference of pH in culture media, including P1: culture media pH 6.5 ± 0.2 , P2: culture media pH 8.5 ± 0.2 and P3: culture media pH 10.5 ± 0.2 . The second factor was the difference of salinity in culture media i.e. S1: salinity of 0 ‰, S2: salinity of 10 ‰, S3: salinity of 20 ‰, and S4: salinity of 30 ‰.

Culture preparation

The equipment used in this study was sterilized using 70% alcohol to minimize the contaminants that inhibit the productivity of *Arthrospira*. The containers used plastic bottles with capacity of 5 L volume of 36 units. The plastic bottle were sterilized using a potassium permanganate solution (2 mg. L⁻¹). Catfish culture wastewater obtained from catfish farming ponds measuring 2 m x 1 m x 1 m, and high of water media was 20 cm (Figure 1). The density used in the pond was 330 fish.400 L⁻¹ with 150 grams fish⁻¹, maintained for 2 months by providing artificial feed (protein 31%-33%), twice per day at satiation. Catfish culture wastewater was previously sterilized by boiling in an autoclave and then cooled, while the steril wastewater was treated with salinity. In treatments S1, S2, S3 and S4 were added with salt until salinity was obtained according to the treatment. The wastewater media had a pH of 7.3, therefore there was an addition of HCl 1 N of 0.75 ml L⁻¹ in P1 treatment to reach a pH of 6.5. Meanwhile, in treatments P2 and P3, to get a pH of 8.5 and pH 10.5 there was an addition of NaOH 8 N as much as 0.07 ml L⁻¹ and 0.45 ml L⁻¹.

Figure 1. Catfish farming pond

Figure 2. *Arthrospira* cultivation

Arthrospira cultivation.

Arthrospira previously used was cultured in catfish culture wastewater for culture stock with a density of 2 g L⁻¹. The stock was taken as much as 400 ml in 3600 ml of catfish culture wastewater in accordance with treatment. Aeration was used for agitation, the lighting using 36 watt TL lamps for 24 hours day⁻¹ during maintenance (Figure 2). Harvest of biomass. The components of wastewater were total phosphorus 2,6 mg.L⁻¹, total nitrogen 1,9 mg.L⁻¹, total organic carbon 11,4 mg.L⁻¹.

Harvest of the biomass was after exponential phase by filtering. The biomass was dried using an oven for 14 hours at 40 °C (Hidayani et al., 2019). The dry biomass was used for the phycocyanin extraction process.

Phycocyanin extraction

The dry biomass was 0.04 g added by 1 ml of phosphate buffer pH 7, then homogenized and frozen in the freezer for 24 hours at a temperature of -4 °C. After 24 hours from the freezer, thawing process for 15 minutes. Samples were centrifuged for 30 minutes at 3000 rpm. After that, the sediment and the supernatant were separated. The resulting supernatant was phycocyanin which be analyzed using the Bennett and Bogorad method (1973).

The density of *Arthrospira* biomass.

Biomass density measurements were performed at each treatment and 3 replications every day at the same hour. The density of biomass was 1 ml of sample in each treatment with 3 replications. The 1 ml of sample into aluminum bowl. The sample and the aluminum bowl were weighed, then dried in the oven for 14 hours at 40 °C. The sample of water that had dried was weighed again. The dry biomass weight of *Arthrospira* biomass was converted to g L⁻¹.

The growth rate of *Arthrospira* can be calculated using the following formula according to Vonshak (1997):

$$\mu = \frac{\ln N_t - \ln N_0}{t} \times 100\%$$

Note: μ = daily growth rate (% days⁻¹)

t = time (days) from N₀ to N_t

N₀ = initial density (g L⁻¹)

N_t = density at the time t (g L⁻¹)

Measurement of total nitrogen and phosphate content in culture media was carried out at the beginning and the first day after the peak phase of each treatment.

The measurement of phycocyanin refers to Bennett and Bogorad (1973). The absorbed supernatant was measured using a spectrophotometer at wavelengths of 615 nm and 652 nm.

$$\text{C-phycocyanin (mg mL}^{-1}\text{)} = \frac{(\text{OD } 615) - 0.474 (\text{OD } 652)}{5.34}$$

$$\text{Rendement of phycocyanin (mg g}^{-1}\text{)} = \frac{\text{C-phycocyanin} \times V}{\text{DB}}$$

$$\text{Rendement percentage of phycocyanin (\%)} = \text{Rendement of phycocyanin (mg g}^{-1}\text{)} \times 100\%$$

Note: C-phycocyanin = C-phycocyanin concentration (mg mL⁻¹)

V = Solvent Volume (ml)

DB = Dry Biomass (0.04 g)

0.474 and 5.34 = coefficient of extinction (Bennett and Bogorad, 1973)

The results were submitted to simple analysis of variance tests (ANOVA) (p < 0.05) and in the case of significant differences, the means were compared by the Least Significant Differences test (p < 0.05).

RESULTS AND DISCUSSION**Morphology of *Arthrospira***

Arthrospira was cultivated using two different fertilizer media namely technical fertilizer and waste media. The morphology of commercial *Arthrospira* before fertilizer treatment was presented in Figure 4.

The results of the identification of isolates showed that the isolate had a twisted filament shape resembling a spiral (helical). Based on Davis's identification book (1955), it is known that the isolate used in the study was *Spirulina* (*Arthrospira*) *platensis*. *Arthrospira* is cyanobacteria belonging to the order Oscillatoriales which has a filament (trichome) that resembles a spiral (helical) but does not have heterocyst cells (Sze, 1998). Heterocyst cells are special thick-walled cells that play a role in nitrogen fixation from the air (Issa et al., 2014). In this study *Arthrospira* cultured in different media had several linear/straight morphologies.

Based on Figure 2, *Arthrospira* which was cultured on technical fertilizer media has a longer and spiraling morphological form compared to another cultured on waste media. Their filaments have more linear morphological form, some spirals but not too long. According to Astiani et al (2016), *Arthrospira* growth is influenced by nutritional and environmental factors. Wang and Zhao (2005) explained that linearization that occurs in *Arthrospira* is a variation on the genetic level that can be caused by environmental factors such as lack of nutrition and high light intensity. In this study, isolates were cultured with the same light intensity of 2000-3000 lux with a light dark ratio of 0:24 hours. Linear filaments in AW have a lower metabolic rate compared to helical filaments. This is one of the adaptive mechanisms for *Arthrospira* to survive some environmental conditions that are not appropriate.

Yadav et al (2020) showed that helical and linear morphotypes of *Arthrospira* sp. display genomic differences. Vonshak (2000) showed that polyphasic in *Arthrospira* morphotypes can be caused by: growing in agar/solid media, light stress-photoinhibition, irradiation, and temperature, effect of physical and chemical conditions. *Arthrospira* is prokaryotic organism, so it is easy to mutation and change sequences in their genome.

Phylogenetic Tree

The results of the 16S rRNA encoding gene sequences from AF and AW isolates were traced to other *Arthrospira* isolates present in GenBank through the BLAST program. The results of the BLASTn analysis of *Arthrospira* samples cultivated in technical fertilizer and waste media with data in Genbank are presented in Table 1. Table 1 results of the BLAST analysis show the closeness between AF and AW isolates with other isolates in GenBank. It show that *Arthrospira* technical fertilizer isolates and *Arthrospira* waste isolates have the closest homology to *Arthrospira platensis* petH species from Japan with percentage values respectively 100% and 94.3%.

Genetic distance was used to see kinship relationships from *Arthrospira* both AF and AW samples with sequential data from Genbank. AF isolate indicated a genetic distance of 0.068 with AW isolates. AW and AF isolates showed the lowest genetic distance respectively 0.089 and 0.060 with *Arthrospira platensis* petH from Japan. Analysis based on genetic distance showed that both isolates were belong to the same species namely *Spirulina platensis*, however the genetic distance was 0.068 (6.8%) meaning that there are intraspecies variations in the sample caused by mutations.

Phylogenetic tree *Arthrospira* isolates from technical fertilizer and waste media were presented in Figure 5. The phylogenetic tree is a two-dimensional graph showing

relationships between organisms or population classifications based on their evolutionary history. The result of phylogenetic tree construction showed that both samples formed branches with a cluster. Phylogenetic tree from AF and AW isolate sequences formed cluster was separate with several other *Arthrospira* species from GenBank data.

The AF isolates had a close relationship with *Arthrospira platensis* petH species from Japan with a bootstrap value of 95%. Hadiati (2003) states that bootstrap analysis is performed to determine the level of confidence in grouping. Bootstrap value is considered high because according to Hall (2001), a clade can be trusted with a bootstrap value of 90%. In addition, Hillis and Bull (1993) state that bootstrap analysis with values of 70% or higher indicate a reliable grouping. The AW isolates formed a separate branch of AF isolates and *Arthrospira platensis* petH species. Genetically, they had diverse, and adapted to environmental conditions. The AW isolate indicated different strain from AF isolate groups. Ballot et al. (2004) stated that *Spirulina* from the same species and

cultured under different conditions can form a separate subcluster with a bootstrap value of 79%. Zhao et al. (2006) identified and analyzed the number of restriction-modification genes in the cyanobacterial genome, seeing that more restriction-modification genes were found in cyanobacterial filaments (*Anabaena*, *Spirulina* and *Nostoc*) than dispenses (*Synechocystis*, *Synechococcus* and *Prochlorococcus*) this was due to the organism adapting to various environmental conditions, or the many variations in sources of nutrients that cause mutations.

Density and Growth Rate of *Arthrospira* cultured in wastewater of catfish farming

The biomass of *Arthrospira* displayed mechanism of adaptation in culture media. The wastewater media could make different characteristic of growth as like as filament. The maximum densities of *Arthrospira* cultured in wasted water were achieved on a different day. The daily density of *Arthrospira* during culture can be seen in Figure 6.

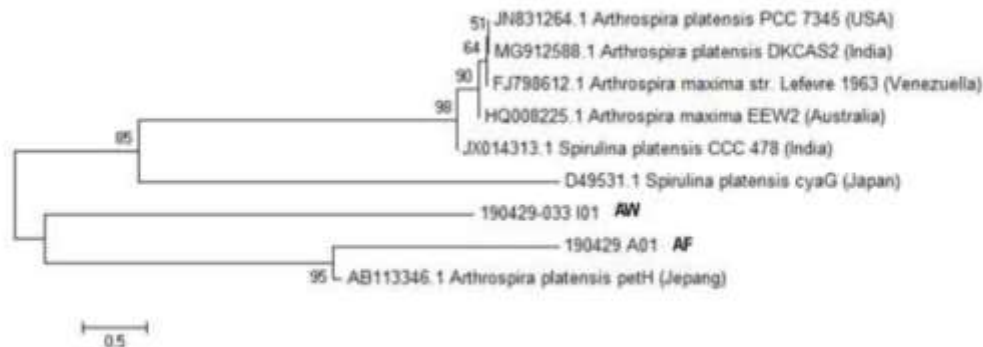

Figure 5. Phylogenetic analysis with 1000 bootstrap AW (*Arthrospira* cultured in waste water media) and AF (*Arthrospira* cultured in fertilizer media)

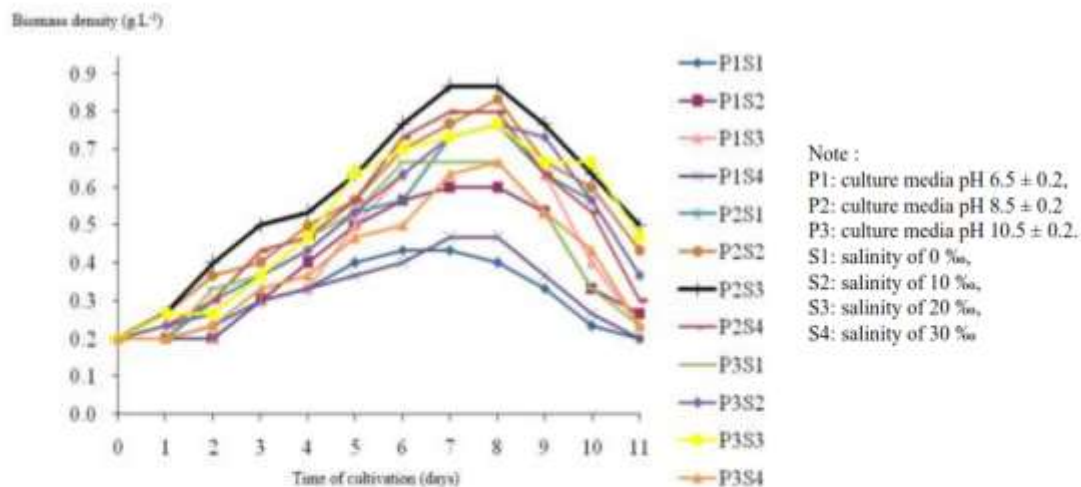

Figure 6. Cell density (dry weight with a moisture content of 1.2%) of *Arthrospira* in catfish rearing pond waste water

The graph presented in Figure 6, it show that in the culture period from day 1 to day 2, *Arthrospira* in each treatment experienced slow growth, because the cells were still adapting to their new environment. The exponential phase for the treatment of P2S2, P2S3, and P3S3 last from day 1 to day 8 of the culture period. In the treatment of P2S1, P2S4, P3S1 and P3S2 take place from 2nd until 8th day of the culture period. While the treatment of P1S1, P1S2, P1S3, P1S4, and P3S4 lasted from 3rd – 8th day of the culture period. The decreasing *Arthrospira* density for the treatment occurred from the day 9 to the day 11 of the culture. Lesmana et al. (2019) explained that the adaptation phase lasts from day 0 to day 1, while the exponential phase occurs from day 1 to day 7, and experiences a stationary phase from day 7 to day 9 then enters the death phase after the 7th day and 9th day. The decrease of density could because of reducing the nutrients in the culture media. Soni et al. (2019), the concentration of nutrients in the media decreased after reaching the peak period. This is due to the higher density of *Arthrospira* in the culture media.

The maximum density of *Arthrospira* could be achieved on different day, between 5 – 8 days after culturing. The mean of maximum density could be 0.433-0.867 g L⁻¹ of dry biomass which cultured in catfish rearing waste water. The maximum cellular density of *A. platensis* which cultured in Nile fish rearing waste water, resulted in the production of 0.22 g L⁻¹ of dry biomass and maximum productivity of 0.03 g L⁻¹ day⁻¹ (Nogueira et al, 2018). The catfish rearing pond waste water has high potential as cultivation media for *Arthrospira* production.

The analysis of variance showed that differences in pH, salinity and interaction between factors (pH and salinity)

significantly affect the maximum density and growth rate of *Arthrospira platensis*. The results of the LSD 0.05 maximum density test and growth rate sequentially were presented in Table 1 and Table 2. LSD 0.05 test results on the main factors of differences in pH, density and growth rate of *Arthrospira platensis* in the P2 treatment (pH 8.5 ± 0.2) were significantly higher than those in the P1 (pH 6.5 ± 0.2) and P3 treatments (pH 10.5 ± 0.2). According to Ismaiel (2016), the highest biomass of *Arthrospira platensis* is produced in media with a pH of 8.5-9.5. Although *Arthrospira platensis* can tolerate a wide pH range, a pH range farther from its optimal pH can reduce its growth rate. A low growth rate will also cause low biomass production.

Furthermore, the different salinity treatment factors showed that the maximum density and growth rate in treatment S3 (salinity of 20 ‰) were significantly higher compared to S1 (salinity of 0 ‰), S2 (salinity of 10 ‰) and S4 (salinity of 30 ‰) treatments. The S1 and S4 treatments were not significantly different and were the treatments that produced the lowest density compared to other treatments. Table 1 and Table 2 showed that the highest density and daily growth rate was found in the S3 (salinity of 20 ‰) treatment. This is supported by the results of Kouhgard et al. (2015), that *Arthrospira platensis* cultured on Conway media was able to produce the highest density of 912.07 mL⁻¹ cells at a salinity of 20 ‰. While the density and growth rate between S1 and S4 treatments showed no significant difference. This is because the salinity of 0-30 ‰ is still within the range of salinity that can be tolerated by *Arthrospira*. Ughy et al. (2015) said that *Arthrospira platensis* is one of the species of *Cyanobacteria* that can grow in an euryhaline environment.

Table 1. Maximum density of *Arthrospira platensis* (g L⁻¹)

Single Influence of pH (P)	Single Influence of Salinity (S) (LSD 0.05 = 0.107)				Main influence of pH (P) (LSD 0.05=0.053)
	S1(0 ‰)	S2 (10 ‰)	S3 (20 ‰)	S4 (30 ‰)	
P1 (pH 6.5)	0.433 ^a	0.633 ^b	0.767 ^{cdef}	0.467 ^a	0.575 ^a
P2 (pH 8.5)	0.767 ^{cdef}	0.833 ^{ef}	0.867 ^f	0.800 ^{def}	0.817 ^c
P3 (pH 10.5)	0.667 ^{bc}	0.733 ^{bode}	0.767 ^{cdef}	0.700 ^{bcd}	0.717 ^b
Main influence of Salinity (S) (LSD 0.05=0.062)	0.622 ^a	0.733 ^b	0.800 ^c	0.656 ^a	

Table 2. The growth rate of *Arthrospira platensis* cultured in pH and salinity treatment(% day⁻¹)

Single Influence of pH (P)	Single Influence of Salinity (S) (LSD 0.05 = 3.224)				Main influence of pH (P) (LSD 0.05=1.612)
	S1(0 ‰)	S2 (10 ‰)	S3 (20 ‰)	S4 (30 ‰)	
P1 (pH 6.5)	14.333 ^a	18.659 ^{cd}	19.192 ^{cde}	13.348 ^a	16.383 ^a
P2 (pH 8.5)	18.343 ^{bcd}	20.570 ^{de}	22.026 ^e	20.723 ^{de}	20.416 ^b
P3 (pH 10.5)	20.023 ^{de}	19.527 ^{cde}	20.623 ^{de}	16.417 ^{abc}	19.147 ^b
Main influence of Salinity (S) (LSD 0.05=1.861)	17.566 ^a	19.585 ^b	20.614 ^b	16.829 ^a	

Note:

‰ mean part per thousand (ppt), it is not percent (%). Salinity of fresh water (0 ppt), brackish water (5-20 ppt) and sea water (more than 25 ppt). The salinity used in this study still supports the growth of *Arthrospira* (Vonshak, 1997).

The interaction between pH and salinity factors showed that the density and growth rate in treatment P2S3 (pH 8.5 ± 0.2 and salinity of 20 ‰) were significantly higher compared to other treatments. At maximum density, treatment P2S3 was not significantly different from treatments such as P1S3, P2S1, P2S2, P2S4, and P3S3. While in the growth rate, treatment P2S3 was not significantly different from P1S3, P2S2, P2S4, P3S2 and treatments P3S3. Table 1 and Table 2 show that treatment P2 (pH 8.5 ± 0.2) is more dominant causing higher density and growth rate of *Arthrospira platensis* despite being in different salinity ranges. As for the treatments P1 (pH 6.5 ± 0.2) and P3 (pH 10.5 ± 0.2) provide the highest density when combined by the treatment S3 (salinity 20 ppt). The treatment of P1, P2, and P3 (pH 6.5 ± 0.2 , 8.5 ± 0.2 , and 10.5 ± 0.2) and S1, S2, S3 and S4 treatments (salinity of 0 ‰, 10 ‰, 20 ‰, and 30 ‰) still support the growth of *Arthrospira platensis* with the best treatment found in the combined treatment P2S3 (pH 8.5 ± 0.2 with salinity of 20 ‰).

Mismatch of pH will cause lysis and can change the shape of pigment growth (Hariyati, 2008). The process of photosynthesis affects the pH value. In daylight, aquatic plants release carbon dioxide from water for use in photosynthesis. The release of carbon dioxide by plants occurs through respiration. When carbon dioxide is released, carbonate builds up and hydrolyzed so that the pH of the water will increase (Boyd, 1990). Prasadi (2018) showed that growth of *Arthrospira* could be inhibited if it was in the pH range above 10.5 or less than 7. Salinity is one of the factors that can influence osmotic pressure for *Arthrospira* as like as others of microalgae. Pisal and Lele (2005) microalgae can experience cell shrinkage in conditions outside the cell salinity higher than inside the cell (hypertonic), and vice versa under conditions of low salinity outside the cell (hypotonic) cell swelling will occur due to water molecules outside moves into the cell. This condition affects the process of photosynthesis, and makes microalgae to produce secondary metabolites in the form of β -carotene to sustain life against changes in salinity in culture media. While in isotonic conditions, cell fluid is isotonic to its external media which causes low active ion transport and osmoeffector exchange, making the Na-K-ATPase enzyme activity at a maximum level and more energy will be utilized for growth (Rahmawati et al., 2012). The optimal combination of pH and salinity causes the growth of *Arthrospira* to be maximal. The optimal salinity range for *Arthrospira* is between 15-20 ‰, from the related research showed that the results of *Arthrospira* culture with 20 ‰ of media salinity, pH 7.5-8.5 using fertilizer media (0.010 g L^{-1} TSP, 0.030 g L^{-1} Urea, and 0.030 g L^{-1} ZA) and a culture periode of 9 days produced a dry weight of *Arthrospira* of 0.0375 g L^{-1} (Prasadi, 2018).

Rendement of phycocyanin

The rendement of *Arthrospira* was presented in Table 3. The pH condition of maintenance media can be affect of protein content in *Arthrospira* cells. The results of LSD $_{0.05}$ on the main factor of pH showed that the rendement of phycocyanin *Arthrospira* in treatment P2 was significantly

higher compared to other treatments. Taufiqurrahmi et al. (2017), the amount of *Arthrospira* biomass influences the high content of phycocyanin. Table 1 showed that the highest of *Arthrospira* biomass was found in treatment P2. It showed that the highest *Arthrospira* biomass produced the highest rendement of phycocyanin (Table 3). The culture medium of *Arthrospira* pH of 8.5 produced the highest C-phycocyanin content (Ismail et al., 2016). Rahmawati et al. (2017) said that the higher of C-phycocyanin followed the higher of rendement of phycocyanin.

LSD $_{0.05}$ showed that the main factor of salinity showed the rendement of phycocyanin in treatment S3 (salinity of 20 ‰) was significantly higher than other treatments. It is thought that the difference in salinity treatment has an impact on the external osmotic pressure of *Arthrospira* cells which results in changes in cell composition especially phycocyanin. Sodium will flow into the cell and cause the release of phycobilin (phycocyanin, phycocyanin and allophycocyanin) from PS II (Photosystem II) and stop the electrons transporting to PS I (Photosystem I) followed by activation of the protective mechanism. *Arthrospira* will produce carbohydrates to balance intracellular osmotic pressure and require more energy to remove sodium ions from cells. In this case it will produce ammonium assimilation causes inhibition of protein synthesis (Zhou et al., 2017).

The environment includes the availability of nutrients, pH, salinity, light and temperature can affect the growth and accumulation of biopigments from microalgae (Sharma and Tiwari, 2014). The condition of culture media is able to influence the growth phase of *Arthrospira*, causing changes in the composition and proportion of phycobilin (phycocyanin, phycocyanin and allophycocyanin) (Simeunovic et al., 2013). The results of the LSD $_{0.05}$ was showed that the rendement of phycocyanin *Arthrospira* on the interaction between factors in treatment P2S3 was significantly higher than in other treatments, but it was not significantly different from treatment P2S2. This showed from the density and growth rate of *Arthrospira*. The increasing salinity will cause maintenance media to be hypertonic towards cells and result in poor absorption of nutrients by cells. These cells could reduce in protein and increase in carbohydrates from *Arthrospira* cells (Ravelonandro et al., 2011).

Production of phycocyanin was able to reach 12.4 % - 17.6% of biomass dry weight of *Arthrospira* cultured in Zarrouk Medium (ZM) (Prates et al., 2018; Garcia-Lopez et al., 2020). There are several factors that affect the rendement of phycocyanin include temperature, extraction time, mixing rate, biomass, type of solvent and the ratio of biomass to the solvent (Taufiqurrahmi et al., 2016). The content of phycocyanin in cyanobacteria increases when grown in low light intensity. Phycocyanin is a pigment associated with protein, polar and water soluble. The protein content of microalgae are influenced by environmental conditions such as temperature, age of culture, light intensity, pH, salinity, and nutrient limits (especially nitrogen). Nitrogen is an essential element needed for the synthesis of accessory pigments and

chlorophyll. When microalgae are growing fast, it requires large amounts of nitrogen and could consume phycocyanin as an alternative source of nitrogen for the production of biomass (Hsieh-Lo et al., 2019). It must be optimized for biomass production and phycocyanin content. The higher concentration of phycocyanin will be followed by the rendement of phycocyanin. In this study, the phycocyanin content is lower than previous study, because of different media for culturing *Arthrospira*. The nutrient from ZM

(pro analysis substances) is more complete for growing and forming phycocyanin than waste water catfish pond media, especially the trace mineral in ZM.

Reduction of Total Nitrogen and Phosphate Content

The percentage reduction of total nitrogen in the culture media was presented in Table 4.

Table 3. Phycocyanin (%) yield in *Arthrospira* dry biomass at 8 days after inoculation

Single Influence of pH (P)	Single Influence of Salinity (S) (LSD _{0.05} = 0.194)				Main influence of pH (P) (LSD _{0.05} =0.096)
	S1	S2	S3	S4

P3	82.940 ^{bcd}	81.143 ^a	84.950 ^{ef}	84.813 ^{ef}	83.462 ^b
Main influence of Salinity (S) (LSD _{0.05} =0.745)	82.590 ^a	83.856 ^b	84.712 ^c	82.603 ^a	

The mechanism for removing nitrogen in water is determined by several factors, including bacterial activity (Gersberg et al., 1986), uptake by plants (Breen, 1990) and evaporation (Sanchez-Monedero et al., 2001). In Cyanobacteria, nitrogen is a macronutrient that plays an important role in the formation of biochemical compounds such as nucleic acids (DNA, RNA), amino acids (protein) and pigments (chlorophyll and phycocyanin) (Markou et al., 2014). The results of the LSD_{0.05} on the main pH factor showed that the reduction in total nitrogen content in *Arthrospira* culture media in treatment P2 was significantly higher than in treatments P1 and P3. This is due to the higher density of *Arthrospira* in treatment P2 compared to other treatments, so that the utilization of nitrogen by *Arthrospira* in culture media is greater than others. Markou et al. (2014) showed that the higher density of *Arthrospira* could be higher the absorption of nutrients including nitrogen.

The value of reducing total nitrogen content in S3 treatment was significantly higher than for other treatments. This showed that treatment S3 caused *Arthrospira* to absorb nitrogen higher than other treatments in line with the high density and rendement of phycocyanin *Arthrospira* obtained in this study. Jabeen and Ahmad (2011) showed that salinity in culture media influences nitrogen absorption and protein biosynthesis. Reduction of total nitrogen content in *Arthrospira* culture media due to interactions between pH and salinity factors showed that treatment P2S3 was significantly higher than other treatments. With the optimal conditions (pH and salinity),

Arthrospira is able to make maximum use of nitrogen. This can be seen from the highest density, growth rate and rendement of phycocyanin found in treatment P2S3. The amount of nitrate and phosphate decreases with increasing growth of *Chlorella vulgaris* and *Arthrospira platensis* (Sayadi et al., 2016). This is because algae have the ability to absorb nutrients such as nitrogen and phosphate are use to carry out photosynthesis and protein production. Reduction of phosphorus content in waters is influenced by the process of absorption, complexation, deposition and assimilation (between microbes and plant biomass) (Tanner et al., 1999).

The results of LSD_{0.05} on the main factor of pH showed that each treatment did not significantly affect the reduction of phosphate content in *Arthrospira* culture medium. Plants can only absorb phosphorus in the form of H₂PO₄ and HPO₄²⁻ free orthophosphate ions (Becquer et al., 2014). The orthophosphate content decreases with increasing media pH. Cerozi and Fitzsimmons (2016) showed the orthophosphate content increases in the pH range from 5.5 to 8.5 and decreases when pH 10. The fall in the orthophosphate content at pH 10 is due to an increase in calcium phosphite formation. The value of reducing the phosphate content in *Arthrospira* culture medium was presented in Table 5.

The salinity factor, administration of different salinity in each treatment has no significant effect on reducing the phosphate content. Bassin et al. (2011) explained the reduction of phosphorus will be inhibited when a combination of Cl⁻ and nitrite and Cl⁻ concentration more

than 2.5 g L^{-1} . The interaction effect of differences in pH and salinity, each treatment had no significant effect on reducing phosphate content. Hua-Sheng et al. (1995) showed that the utilization of Dissolved Organic Phosphorus (DOP) can be through active uptake into cells or by extracellular mineralization by phosphatase enzymes. However, most DOP compounds cannot be assimilated directly with microalgae because they have been mineralized. Markou et al. (2014) stated that phosphorus is a macronutrient that plays an important role in the preparation of nucleic acids (RNA and DNA), phospholipids and energy-carrying molecules (ATP). The phosphorus content in plants is lower than Ca, N, and K (Sasaqi et al., 2018). Although the analysis of variance shows that the results are not significantly different, but the highest phosphate reduction still existed in treatment P2S3.

Morphology of *Arthrospira* in various pH and salinity media

Morphology of *Arthrospira* was affected by increasing or decreasing physical or chemical factors in their culture media. Salinity and acidity value combination at this study didn't change the filament of *Arthrospira* significantly as their filament of *Arthrospira* under microscope with 100x magnification (Figure 7). The morphological form of *Arthrospira* were not different in all of pH and salinity treatments. The waste water catfish pond media could affected in the linerizing filament. This study indicated that salinity and acidity of culture media didn't effect on various form filament, either straight and helical.

Table 5. Reduction of phosphate content in *Arthrospira* culture medium (%)

Single Influence of pH (P)	Single Influence of Salinity (S)				Main influence of pH (P)
	S1	S2	S3	S4	
P1	70.500	71.667	73.000	72.333	71.875
P2	74.667	74.000	74.667	72.667	74.000
P3	70.333	70.333	73.667	72.667	71.750
Main influence of Salinity (S)	71.833	72.000	73.778	72.556	

Figure 7. Morphology of *Arthrospira* in catfish wastewater culture media at several treatment of pH and salinity

The straight filaments were observed for *Arthrospira* strains during two years of cultivation, and their presence in *Arthrospira* sp. Nigrita C1 cultures was constant. The various morphological plasticity, greatly influenced by the growth stage and exogenous parameters, such as temperature and light intensity, was observed for *Arthrospira* strains (Papapanagiotou and Gkelis, 2019). There are indications that adaptability to change in environmental conditions is relatively rapid and also subsequent changes at the genetic level can be realized quickly. This means that we can easily find different genotypes in various stable, ecologically different habitats. Morphologically similar strains were cultured for a long time under uniform and stable conditions (Komarek, 2016). But the morphological changes couldnot be effected by acidity and salinity of culture media.

Conclusions

Arthrospira that is cultured on waste media (observed in liquid culture) indicated some short and linear filaments. Identified *Arthrospira* had a genetic distance of 6.8% between AF and AW isolates. AF isolates had a close relationship with *Arthrospira platensis* peth species originating from Japan (bootstrap value of 95%) while AW isolates form phylogenetic branches which are separated from AF isolates and *Arthrospira platensis* peth species originating from Japan (bootstrap value 85%). The catfish culture wastewater media at different pH and salinity affects the density, growth rate and rendement of phycocyanin *Arthrospira platensis*. The highest density, growth rate and rendement of phycocyanin was in P2S3 treatment (pH 8.5 ± 0.2 and salinity of 20 ‰) which produced a maximum density of 0.867 g L^{-1} , growth rate of $22.026\% \text{ day}^{-1}$ and the rendement of phycocyanin of 11.334 %.

ACKNOWLEDGMENT

We thank staff at Aquaculture Laboratory and Plant Physiology Laboratory, Faculty of Agriculture, Sriwijaya University, Indonesia. The authors also acknowledge the contribution of the Sriwijaya University for Profession Research Grant (No. 0144.25/UN9/SB3.LP2M.PT/2019).

Table 1. The author's answers to the reviewers' questions

No	Reviewer's Questions	Author's Answer
From Reviewer C		
1	<p><i>There is no control+/- to compare the results of growth, phycocyanin and identity blasts. The authors need to bring the results of CA (commercial Arthrospira) and AF to see the differences between the treatments with Control. The comparison only in morphology has been brought. They should bring this comparison in the other factors they worked like growth, phycocyanin, N and P reduction etc.</i></p>	<p>We didn't give control+/- to compare the result of growth, phycocyanin and identity blast in our study, because we didn't have the commercial Arthrospira cultivation. We grew the commercial Arthrospira (in commercial name 'Spirulina') in fertilizer media. The picture of CA morphology was taken at the first time commercial isolates arrived. The picture of AF morphology was taken after cultivation of the CA isolates in fertilizer media, and the AW morphology picture was taken after cultivation of AF isolates in waste water media. To compare the result of growth, phycocyanin, identity blast, N and P reduction, we used data from references. Thank you.</p>
2	<p><i>Still it's not clear how the pH and salinity along with some other factors in the waste water can change genome of an organism during a week.</i></p>	<p>We tried to cultivate the biomass of Arthrospira in fertilizer media for scaling up, and the biomass of Arthrospira from fertilizer media was continued to cultivating in waste water media. The cultivation of Arthrospira needed several week for scaling up. We used fertilizer medium for cultivation for 2 weeks, isolated for purification in agar media for 3 weeks, and transferring in liquid media (fertilizer media) and growing them in 50 ml volume Erlenmeyer for 8 days, and then they had been scaling up to 1 liter. The stabile cultivation of Arthrospira (fertilizer media) was transferred in waste media cultivation. Production time of Arthrospira in same scale of cultivation was 8 days. The Arthrospira cultured in waste medium was isolated to agar media enriched with waste water from catfish pond.</p> <p>We didn't know that the waste water can change genome of Arthrospira. We extracted the DNA of AF and AW from agar media. The DNA genomes were amplified by the 16SrRNA primer (Marchesi, 2003). The amplicons were sequenced for analyzing their genetic drift</p>

		<p>for different cultivation media. The different of morphotypes between AF and AW can be caused polyphasic based on physiology of adaptation to heterotrophic media (waste media) only or changing their genomes. The data showed that it was genetic drift because of their different sequences after aligned with data from gene bank.</p> <p>Yadav et al (2020) showed that helical and linier morphotypes of <i>Arthrospira</i> sp. display genomic differences. Vonshak (2000) showed that polyphasic in <i>Arthrospira</i> morphotypes can caused by: growing in agar/solid media, light stress-photoinhibiton, irradiation, and temperature, effect of physical and chemical conditions. Once a strain has converted to the straight form, either naturally or due to physical or chemical treatments, it does not usually revert to the helical form. This may be due to a mutation affecting some trichomes under certain growth conditions. The common occurrence of straight trichomes in cultures of <i>Arthrospira</i> also suggests that the helical character may be carried on plasmids, but no one has yet demonstrated the existence of plasmids in <i>Arthrospira</i> or <i>Spirulina</i> strains. <i>Arthrospira</i> is prokaryotic organism, so it is easy to mutation and change sequences in their genome.</p>
From Reviewer V:		
1.	What the source of <i>Arthrospira</i> ?	It was from commercial <i>Spirulina</i> “TopSpiraSpirulina” East Jakarta
2	Why not use a specific Zarrouk medium?	Because the commercial <i>Spirulina</i> was cultured in technical fertilizer media directly, and we used the media based on our previous study about technical media in laboratory scale. The result showed that this technical media can substituted Zarrouk Medium for growing <i>Spirulina</i> biomass in more cheap medium than ZM.
3	In Table 1 and 2: Salinity 10,20 and 30% means 100,200 and 30 grams per liter is very high and this under stress which means the reduction of growth rate.	‰ mean part per thousand, it is not percent (%), so.. they are still range of salinity between fresh water (0 ppt), brackish water (5-20 ppt) and sea water (more than 25 ppt). The salinity used in this study still supports the

		growth of <i>Arthrospira</i> . They can grow between 0-60 ppt (Vonshak, 2000)
4	How is this given growth rate?	The reason is the same of no 3. Thank you
5	What are the components of wastewater?	Total phosphorus 2,6 mg.L ⁻¹ , total nitrogen 1,9 mg.L ⁻¹ , total organic carbon 11,4 mg.L ⁻¹ : the source of N, P, C for growing
6	Figure 4 is not clear, should be redrawn for high quality.	We are very sorry, because we don't have the high quality picture
7	Attention to references	We had corrected the references. Thank you.
8	There are some notes in the text.	We had corrected based on some notes in the text. Thank you

Abstract. Wijayanti M, Syaifudin M, Yulisman, Nurianti Y, Hidayani A, Gofar N. 2020. Characterization of *Arthrospira platensis* cultured in wastewater of *Clarias* catfish farming media: DNA barcode, helical form, growth, and phycocyanin. *Biodiversitas* 21: 5872-5883. *Arthrospira* production technology in catfish waste media can be an alternative to reduce environmental pollution. However, some environmental factors such as nutrition, light, and water content can influence characterization of *Arthrospira* at the genetic and physiologic level. *Arthrospira platensis* is one of the phycocyanin-producing cyanobacteria and can be cultured using catfish culture wastewater. Water quality especially pH and salinity can effect of growth rate and residue of phycocyanin from *Arthrospira platensis*. This study aimed to identify the species and morphological forms of *Arthrospira* cultured using technical fertilizer and waste media, as well as to know the phylogenetic trees between species in this study and the GeneBank based on the 16S rRNA gene, and determine the optimum of pH and salinity required in the medium of catfish culture wastewater to phycocyanin maximum production of *Arthrospira*. The optimization of pH and salinity method used Completely Randomized Design (CRD) factorial with 2 factors consisting of the first factor with 3 treatments and the second factor with 4 treatments and 3 replications. The first factor was pH of culture medium i.e. pH 6.5 ± 0.2, pH 8.5 ± 0.2 and pH 10.5 ± 0.2. The second factor was salinity of culture medium, that was salinity 0 ppt (parts per thousand‰), 10 ppt, 20 ppt, and 30 ppt. Parameters observed in *Arthrospira* include density, growth rate, rendement of phycocyanin, and decreased total nitrogen and phosphate content in culture media. The results showed that morphology *Arthrospira* cultured on technical fertilizer media (AF) had a longer and helix filament compared to *Arthrospira* cultured on waste media (AW) which showed several linear and shorter filaments. Both samples have a genetic distance of 0.068 (6.8%). Phylogenetic trees indicated that AF had a close relationship with *Arthrospira platensis* petH from Japan (bootstrap value 95%). While AW formed a separate sub-cluster of AF isolates and *Arthrospira platensis* petH from Japan (bootstrap value of 85%). The best treatment in this study was P2S3 (pH 8.5 ± 0.2 with salinity 20 ppt), which produced 0.867 grams maximum density, growth rate of 22.026 %·day⁻¹ and 11.347 mg·g⁻¹ rendement of phycocyanin.

Keywords: 16S rRNA, *Arthrospira*, catfish culture wastewater, DNA barcode, pH, phycocyanin, phylogenetic analysis, salinity, *Spirulina*

INTRODUCTION

Arthrospira is a genus of cyanobacterial microalgae, commonly known under the taxonomically incorrect brand name '*Spirulina*' (Papapanagiotou and Gkelis 2019). The cyanobacterial genus *Arthrospira* Stizenberger ex Gomont 1892 contains at present 23 species, along with 12 infraspecific taxa (Guiry and Guiry 2010). They have variety characteristics of molecular, morphology, and physiology that based on polyphasic approach. Various genotypes are adaptable to various specialized ecosystems. The combination of different methods should be based on molecular sequencing as the basic approach, to which must be added other criteria (morphological, ecological) if they are available and which are distinct and recognizable in cyanobacterial populations. A polyphasic approach to include all the criteria obtained from morphological, biochemical, molecular studies, and phylogenetic to understand cyanobacterial classification as like as *Arthrospira* classification (Komárek 2018).

Recent studies have shown that *Arthrospira* can be used for treating wastewater, including effluent from fish culture, because the biomass can metabolize the nutrients and remove the pollutant from aquaculture effluent efficiently (Zhang et al. 2019). Industrial and processing wastes and by-products for culturing *Spirulina* (*Arthrospira*) are also being considered as alternative culture media, as like as aquaculture wastewater (Wijayanti et al. 2018; Widiantoro et al. 2018; Ragaza et al. 2020). Aquaculture could apply an integrated strategy of simultaneously treating aquaculture effluent while producing the biomass to supplement fish diets. The nutrient composition in their biomass depends on their environmental factor for growing biomass. Their character could be different from the various media for growth.

Basically, *Arthrospira*'s morphology is characterized by trichomes that circular regularly (helical). However, abnormal morphology can also occur in *Arthrospira* as a circular shape that is irregular even linear. In some cultivation conditions, linear filaments can spontaneously return to the helix. However, there are significant

differences in morphology, ultrastructure, physiology, biochemistry, and genetic characteristics between the original filament and the linear filament but not the difference between the original and the returned filament. Linearization in *Arthrospira* is a variation on the genetic level that can be caused by several environmental factors such as nutrition, light, and content of water media for growth (Wang and Zhao 2005). According to Liu et al. (2016), DNA barcoding has developed as a reliable technology for identifying species based on variations in the sequence of standard DNA regions. This method is used successfully in a variety of biological applications including finding cryptic species, detecting invasive species, and identifying plants. DNA barcoding is a simple short genome sequence amplified via PCR using appropriate primers (Adamowicz 2015). DNA barcoding using the 16S rRNA gene has been widely used to determine bacterial DNA characterization. Therefore, identification of *Arthrospira* using the 16S rRNA gene needs to be done to get the characterization of *Arthrospira* that is cultured on technical fertilizer and waste media and determine the phylogenetic tree structure that has been recorded in GeneBank.

Culture of *Arthrospira* (*Spirulina*) in *Clarias* pond farming wasted water could have specific characterization for optimal pH value and salinity. Their adaptation to grow in organic wastewater makes change in bioactive and important compound production. Their biomass has a nutritional value of 55-70% protein, 6-10% lipid 20% carbohydrate, besides being rich in minerals, vitamins, and pigments (Borowitzka et al. 2016; Vernes et al. 2015). Some color pigments that can be produced such as phycocyanin (blue pigment), allophycocyanin (blue-green), and phycoerythrin (red pigment) (Sharma and Tiwari 2011; Vernes et al. 2015). Phycocyanin is pigment in *Arthrospira* which has functions as an antioxidant (Prenantyo and Limantara 2008), a source of food coloring, cosmetics, pharmaceuticals, and drugs (Tang et al. 2020; Tiwari and Tiwari 2020), anti-inflammatory, antioxidative and anticancer (Liu et al. 2013). One of the factors that influence phycocyanin levels is biomass (Taufiqurrahmi et al. 2017). The pH and salinity of culture media can affect the biomass of *Arthrospira* (Ciferri 1983; Marek et al. 1987; Planes et al. 2002). Ismaiel et al. (2016) showed that the diversity of the chemical composition of biomass is influenced by the pH of the growth media. Value of pH and environmental factors, especially salinity, influence the productivity of cell biomass, photosynthesis, shape, and flow of cellular metabolic activity that affect the dynamics of cell composition (Hu 2004). The optimal pH value for growth of *Arthrospira* sp is 7-10.5 (Hariyati 2008), and salinity from 15-30‰ (Thajuddin and Subramanian 2005). The salinity and pH value of *Arthrospira* culture media have been known to affect the morphology of the filament.

The aims of this study are characterizing morphological forms and DNA barcode based on the 16S rRNA gene of *Arthrospira* (*Spirulina*) cultured in fertilizer and waste water effluent of *Clarias* pond farming media, and determining optimal pH value and salinity of culture media for growth and phycocyanin production, especially in

Clarias pond farming waste water media and morphological changes of their filament.

MATERIALS AND METHODS

Arthrospira cultured in agar media

Bacto agar was weighed as much as 2 g dissolved in 100 mL of water. The water used was swamp water and catfish culture waste that has been filtered and sterilized using an autoclave. Sterilized swamp water was then added with 0.02 gram $MgSO_4$ fertilizer; $CaCl_2$ 0.004 gram; EDTA 0.008 gram; urea 0.03 gram; ZA (Sulphate of Ammonia) 0.132 grams; 0.4 gram baking soda; AB solution 1 mL mix A solution (Calcium Nitrate 64.26%, Potassium Nitrate 33.66%, Fe EDTA 2.08%) 2 grams / 10 mL and B solution (Potassium dihydro phosphate 25.83%, Ammonium sulfate 9.41%, Potassium sulfate 2.78%, Magnesium sulfate 60.91%, Cupric sulfate 0.03%, Zinc sulfate 0.12%, Boric acid 0.31%, Manganese sulfate 0.62%, Ammonium heptamolybdate 0.01%) 2 grams/10 mL water and TSP (Triple Super Phosphate) 0.05 grams were then homogeneous using magnetic stirrers. Next, wasted water was sterilized by an autoclave then cooled. Bactoagar was added to the technical fertilizer and waste solution to be homogenized using a magnetic stirrer and then boiled using a hot plate until all the ingredients dissolve and then autoclave again. The agar media was made with a pH of 7 and a salinity of 10 ppt or 10 g.L⁻¹ (Hidayani et al. 2019).

Arthrospira cultivated in liquid media was taken 100 µL using micropipette and spread to the surface of a petri dish containing bactoagar media by using a sterilized spreader rod. Petri dishes were wrapped in wrapping plastic and then given a lamp lighting (light intensity 2000-4000 lux) with a dark: light ratio = 0: 24 hours. *Arthrospira* was observed every day until it grows blue-green. After growing, *Arthrospira* was re-cultured in agar media by the 4 quadrant scratch method. The cultures were used as isolate samples for determining DNA barcodes. The biomass of *Arthrospira* was isolated from commercial *Spirulina* TopSpira East Jakarta, Indonesia.

The commercial *Arthrospira* was cultured in technical fertilizer media directly, and we used the media based on our previous study about fertilizer media on laboratory scale (Laboratorium of Aquaculture, Faculty of Agriculture, Sriwijaya University). The result showed that this fertilizer media can substitute Zarrouk Medium (ZM) for growing *Spirulina* biomass in cheaper medium than ZM (Wijayanti et al. 2018).

DNA extraction

DNA extraction was carried out according to procedures in which there was a Presto TM Mini gDNA Bacteria Kit (Geneaid Biotech Ltd.). DNA extraction consisted of several stages: sample preparation, lysis, purification, and precipitation or washing. The sample used was 0.15 grams of wet weight for one extraction (Geneaid manual).

DNA amplification

The process of DNA amplification using the PCR (Polymerase Chain Reaction) method was performed using 2 µL forward primers 63T (5'-CAC AGGC CTA CAC ATC CAA GTC-3') and reverse primers 1387T (5'-CGG CCG WGT GTA CAA GGC-3') (Mandoh et al. 1998). The total composition of the PCR mixture was 50 µL, which consisted of 25 µL Go Taq Green, 13 µL NFW (Nucleic Free Water) and 8 µL *Arthrospira* DNA extraction template. DNA amplification was carried out in stages: the initiation cycle at 95°C for 3 minutes, followed by 30 denaturation cycles at 94°C for 30 seconds, annealing at 55°C for 30 seconds, then the extension stage at 72°C for 1 minute, and the final stage 72°C for 3 minutes (Lee et al. 2005).

Electrophoresis

Electrophoresis was carried out using 1% agarose gel at 75 V for 33 minutes. Agarose that has been electrophoretic was immersed with a mixture of 10 µL diluted ethidium bromide and 100 mL TAE. TAE is buffer solution for 30 minutes without exposure to light. The results were visualized through gel documentation by observing DNA migration using a transilluminator UV.

Gene sequencing

Arthrospira DNA samples that were successfully amplified using PCR were then sequenced in the fragments of 16S rRNA gene. The amplified products were sequenced through the services of the Macrogen Institute in Jakarta. The DNA sequences obtained in the form of data format were aligned using MEGA 6.0 software and then uploaded through the Basic Local Alignment Search Tool (BLAST) program. BLAST was a program to search for and analyze the homology of an unknown sequence, in this case the 16S rRNA gene, within a database that its homology can be identified with another gene *Arthrospira* 16S rRNA gene sequences registered in the GenBank database. The genetic distance and phylogenetic trees between genes were constructed using the Neighbor-Joining (NJ) method. The phylogenetic tree was constructed through the Mega 6.0 software application using the Neighbor-joining (NJ) method of the Maximum Parsimony likelihood model and substitution to include d: Transition + Transversions with 100% bootstrap. Meanwhile, *Arthrospira* morphological form analysis was presented in the form of images and discussed descriptively by referring to the appropriate literature.

Optimization of pH and salinity for growing *Arthrospira* in Catfish farming waste water

The experimental design for optimizing pH and salinity media for growing *Arthrospira* in Catfish farming waste water was a Factorial Completely Randomized Design (CRD) consisting of the first factor with 5 treatments and the second factor with 4 treatments and 3 replications. The first factor was the difference of pH in culture media, including P1: culture media pH 6.5 ± 0.2, P2: culture media pH 8.5 ± 0.2, and P3: culture media pH 10.5 ± 0.2. The second factor was the difference of salinity in culture

media (i.e. S1: salinity of 0 ‰, S2: salinity of 10 ‰, S3: salinity of 20 ‰, and S4: salinity of 30 ‰).

Culture preparation

The experiment used in this study was sterilized using 70% alcohol to minimize the contaminants that inhibit the productivity of *Arthrospira*. The containers used plastic bottles with capacity of 5 L, volume of 30 units. The plastic bottle was sterilized using a potassium permanganate solution (7 mg L⁻¹). Catfish culture wastewater obtained from catfish farming ponds (measuring 2 m x 1 m, and high water media was 20 cm) (Figure 1). The density used in the pond was 300 fish/400 L⁻¹ with 100 grams fish⁻¹, maintained for 2 months by providing artificial feed (protein 31%-37%), twice per day at saturation. Catfish culture wastewater was previously sterilized by boiling in an autoclave and then cooled, while the start wastewater was treated with safety. In treatments S1, S2, S3, and S4 were added with salt until salinity was obtained according to the treatment. The wastewater media had a pH of 7.3, therefore there was an addition of HCl 1 N of 0.75 mL L⁻¹ in P1 treatment to reach a pH of 6.5. Meanwhile, in treatments P2 and P3, to get a pH of 8.5 and pH 10.5 there was an addition of NaOH 8 N as much as 0.07 mL L⁻¹ and 0.45 mL L⁻¹.

***Arthrospira* cultivation**

Arthrospira previously used was cultured in catfish culture wastewater for culture stock with a density of 0.1 g L⁻¹. The stock was taken as much as 400 mL in 1600 mL of catfish culture wastewater in accordance with treatment. Aeration was used for aeration, the lighting used 36 watt TL lamps for 24 hours/day¹ during maintenance (Figure 2). Harvest of biomass. The components of wastewater were total phosphorus 7.6 mg L⁻¹, total nitrogen 1.9 mg L⁻¹, and organic carbon 11.4 mg L⁻¹. Harvest of the biomass was after exponential phase by filtering. The biomass was dried using an oven for 14 hours at 40°C (Hidayati et al. 2019). The dry biomass was used for the phycoerythrin extraction process.

Phycocyanin extraction

The dry biomass was 0.04 g added by 1 mL of phosphate buffer pH 7, then homogenized and frozen in the freezer for 24 hours at a temperature of -4 °C. After 24 hours from the freezer, thawing process for 15 minutes. Samples were centrifuged for 30 minutes at 3000 rpm. After that, the solvent and the supernatant were separated. The resulting supernatant was phycoerythrin which he analyzed using the Bennett and Bogorad method (1973).

The density of *Arthrospira* biomass

Biomass density measurements were performed at each treatment and 3 replications every day at the same hour. The density of biomass was 1 mL of sample in each treatment with 3 replications. The 1 mL of sample into aluminam bowl. The sample and the aluminam bowl were weighed, then dried in the oven for 14 hours at 40 °C. The sample of water that had dried was weighed again. The dry biomass weight of *Arthrospira* biomass was converted to g L⁻¹.

Figure 1. Catfish farming pond

The growth rate of *Arthrospira* can be calculated using the following formula according to Venubak (1997):

$$\mu = \frac{\ln N_t - \ln N_0 \times 100\%}{t}$$

Where:
 μ = daily growth rate (% day⁻¹)
 t = time (days) from N₀ to N_t
 N_0 = initial density (g L⁻¹)
 N_t = density at the time (g L⁻¹)

Figure 2. *Arthrospira* cultivation

Recovery percentage of phycoerythrin (%) = Recovery of phycoerythrin (mg g⁻¹) × 100%

Where:
 C = phycoerythrin = C (phycoerythrin concentration (mg mL⁻¹))
 V = Volume (Volume mL)
 DB = Dry Biomass (0.04 g)
 0.474 and 3.34 = coefficient of extraction (Bennett and Bogorad 1973)

The results were submitted to simple analysis of variance tests (ANOVA) (p < 0.05) and in the case of significant differences, the means were compared by the Least Significant Difference test (p < 0.05).

RESULTS AND DISCUSSION

Morphology of *Arthrospira*

Arthrospira was cultured using two different fertilizer media namely technical fertilizer and waste media. The morphology of commercial *Arthrospira* before fertilizer treatment was presented in Figure 3.

Figure 3. Morphological identification results of *Arthrospira* isolates: CA = Commercial *Arthrospira*; AF = commercial *Arthrospira* cultured with technical fertilizer media; AW = commercial *Arthrospira* cultured with waste media (by magnification). Note: a = helical form AF, b = helical form AW, c = straight form AW

The results of the identification of isolates showed that the isolate had a twisted filament shape resembling a spiral (helical). Based on Davis's identification book (1955), it is known that the isolate used in the study was *Spirulina (Arthrospira) platensis*. *Arthrospira* is cyanobacteria belonging to the order Oscillatoriales which has a filament (trichome) that resembles a spiral (helical) but does not have heterocyst cells (See 1998). Heterocyst cells are special thick-walled cells that play a role in nitrogen fixation from the air (Liu et al. 2014). In this study, *Arthrospira* cultured in different media had several linear-straight morphologies.

Based on Figure 2, *Arthrospira* which was cultured on technical fertilizer media has a longer and spreading morphological form compared to another cultured on waste media. Their filaments have more linear morphological form, some spirals but not too long. According to Antizar et al. (2016), *Arthrospira* growth is influenced by nutritional and environmental factors. Wang and Zhao (2007) explained that limitation that occurs in *Arthrospira* is a variation on the genetic level that can be caused by environmental factors such as lack of nutrition and high light intensity. In this study, isolate was cultured with the same light intensity of 2000-3000 lux with a light-dark ratio of 9: 24 hours. Linear filaments in AW have a lower metabolic rate compared to helical filaments. This is one of the adaptive mechanisms for *Arthrospira* to survive some environmental conditions that are not appropriate.

Yadav et al. (2020) showed that helical and linear morphologies of *Arthrospira* sp. display genetic differences. Venubak (2000) showed that polyphasic *Arthrospira* morphotypes can be caused by growing in agarified media, light stress-photosynthesis, irradiation, and temperature, effect of physical and chemical conditions. *Arthrospira* is prokaryotic organism, so it is easy to mutate and change sequences in their genes.

Phylogenetic tree

The results of the 16S rRNA encoding gene sequences from AF and AW isolates were traced to other *Arthrospira* isolates present in GenBank through the BLAST program.

The results of the BLAST analysis of *Arthrospira* samples cultured in technical fertilizer and waste media with data in GenBank are presented in Table 1. Table 1 results of the BLAST analysis show the closeness between AF and AW isolates with other isolates in GenBank. It shows that *Arthrospira* technical fertilizer isolates and *Arthrospira* waste isolates have the closest homology to *Arthrospira platensis* peff1 species from Japan with percentage values respectively 100% and 94.3%.

Genetic distance was used to see kinship relationships from *Arthrospira* both AF and AW samples with segmental data from GenBank. AF isolates indicated a genetic distance of 0.008 with AW isolates. AW and AF isolates showed the lowest genetic distance respectively 0.009 and 0.008 with *Arthrospira platensis* peff1 from Japan. Analysis based on genetic distance showed that both isolates belonged to the same species namely *Spirulina platensis*; however, the genetic distance was 0.005 (0.8%) meaning that there are intraspecific variations in the sample caused by mutations.

Phylogenetic tree *Arthrospira* isolates from technical fertilizer and waste media were presented in Figure 4. The phylogenetic tree is a two-dimensional graph showing relationships between organisms or population classifications based on their evolutionary history. The result of phylogenetic tree construction showed that both samples formed branches with a cluster. Phylogenetic tree from AF and AW isolate sequences formed cluster with separate with several other *Arthrospira* species from GenBank data.

The AF isolate had a close relationship with *Arthrospira platensis* peff1 species from Japan with a bootstrap value of 95%. Hidayati (2003) states that bootstrap analysis is performed to determine the level of confidence in grouping. Bootstrap value is considered high biomass according to Hall (2001), a value can be treated with a bootstrap value of 90%. In addition, Hillis and Bull (1993) state that bootstrap analysis with values of 70% or higher indicates a reliable grouping. The AW isolate formed a separate branch of AF isolate and *Arthrospira platensis* peff1 species. Genetically, they had diverse, and adapted to

environmental conditions. The AW isolate indicated different strains from AF isolate groups. Ballet et al. (2004) stated that *Spirulina* from the same species and cultured under different conditions can form a separate subspecies with a bootstrap value of 79%. Zhao et al. (2006) identified and analyzed the number of restriction-modification genes in the cyanobacterial genome, using that more restriction-modification genes were found in cyanobacterial filaments (*Anabaena*, *Spirulina*, and *Nostoc*) than desquam (*Synechococcus*, *Synechococcus* and *Prochlorococcus*) this was due to the organism adapting to various environmental conditions, or the many variations in sources of nutrients that cause mutations.

Density and Growth Rate of *Arthrospira* cultured in wastewater of catfish farming

The biomass of *Arthrospira* displayed mechanism of

The graph presented in Figure 5, it shows that in the culture period from day 1 to day 2, *Arthrospira* in each treatment-experienced slow growth, because the cells were still adapting to their new environment. The exponential phase for the treatment of P2S2, P3S3, and P3S4 lasts from day 3 to day 6 of the culture period. The treatment of P2S1, P2S4, P3S1 and P3S2 taken place from 2nd until 8th day of the culture period. While the treatment of P1S1, P1S2, P1S3, P1S4, and P1S4 lasted from 3rd - 8th day of the culture period. The decreasing *Arthrospira* density for the treatment occurred from day 9 to day 11 of the culture. Lestiana et al. (2019) explained that the adaptation phase lasts from day 0 to day 1, while the exponential phase occurs from day 1 to day 9, and experiences a stationary phase from day 7 to day 9 then enters the death phase after the 7th day and 9th day. The decrease of density could be caused by reducing the nutrients in the culture media. Some of the reasons of the decrease in density is due to the

water was exhausted on a different day. The daily density of *Arthrospira* during culture can be seen in Figure 5.

Figure 4. Phylogenetic analysis with 1000 bootstrap AW (*Arthrospira* cultured in wastewater media) and AF (*Arthrospira* cultured in fertilizer media)

Figure 5. Biomass density (g L⁻¹) of *Arthrospira* during culture

Figure 5. Cell density (dry weight) with a moisture content of 1.20% of *Arthrospira* in earth rearing pond wastewater

The maximum density of *Arthrospira* could be achieved on different days, between 5 - 8 days after culturing. The mean maximum density could be 0.433-0.907 g L⁻¹ of dry biomass cultured in earth rearing wastewater. The maximum cell density of *A. platensis* which cultured in earth rearing wastewater, resulted in the production of 0.22 g L⁻¹ of dry biomass and maximum productivity of 0.03 g L⁻¹ day⁻¹ (Nugraha et al. 2018). The earth rearing pond wastewater has high potential as cultivation media for *Arthrospira* production.

The analysis of variance showed that differences in pH, salinity, and interaction between factors (pH and salinity) significantly affect the maximum density and growth rate of *Arthrospira* platensis. The results of the LSD_{0.05} maximum density and growth rate sequentially were presented in Tables 1 and 2. LSD_{0.05} test results on the main factors of difference to pH, density, and growth rate of *Arthrospira* platensis in the P2 treatment (pH 8.5 ± 0.2) were significantly higher than those in the P1 (pH 6.5 ± 0.2) and P3 treatment (pH 10.5 ± 0.3). According to Inanaci (2016), the highest biomass of *Arthrospira* platensis is produced in media with a pH of 8.5-9.5. Although *Arthrospira* platensis can tolerate a wide pH range, a pH range further than its optimal pH can reduce its growth rate. A low growth rate will also cause low biomass production.

Furthermore, the different salinity treatment factors showed that the maximum density and growth rate in treatment S3 (salinity of 20 ‰) were significantly higher compared to S1 (salinity of 0 ‰), S2 (salinity of 10 ‰) and S4 (salinity of 30 ‰) treatments. The S1 and S4 treatments were not significantly different and were the treatments that produced the lowest density compared to other treatments.

Table 1. Maximum density of *Arthrospira platensis* (g L⁻¹)

Single influence of pH (P)	Single influence of salinity (S) (LSD _{0.05} = 0.107)				Main influence of pH (P) (LSD _{0.05} = 0.455)
	S1 (0 ‰)	S2 (10 ‰)	S3 (20 ‰)	S4 (30 ‰)	
P1 (pH 6.5)	0.433*	0.433*	0.787**	0.467*	0.375*
P2 (pH 8.5)	0.787**	0.907**	0.908**	0.817**	0.817**
P3 (pH 10.5)	0.467*	0.733**	0.787**	0.708**	0.717*
Main influence of salinity (S) (LSD _{0.05} = 0.063)	0.422*	0.733*	0.800*	0.656*	

Table 2. The growth rate of *Arthrospira platensis* cultured in pH and salinity treatment (% day⁻¹)

Single influence of pH (P)	Single influence of salinity (S) (LSD _{0.05} = 1.226)				Main influence of pH (P) (LSD _{0.05} = 0.412)
	S1 (0 ‰)	S2 (10 ‰)	S3 (20 ‰)	S4 (30 ‰)	
P1 (pH 6.5)	14.33**	14.25**	13.02**	13.24**	10.382*
P2 (pH 8.5)	16.14**	16.75**	22.01**	20.72**	20.416*
P3 (pH 10.5)	20.023**	19.327**	20.023**	19.417**	19.147*
Main influence of salinity (S) (LSD _{0.05} = 1.201)	17.368*	18.587*	20.014*	19.629*	

Note: ** = means per pair treatment (pp), * is not pair (p). Salinity of treatment (0 ppt, brackish water (5-20 ppt), and sea water more than 25 ppt). The salinity used in this study will support the growth of *Arthrospira* (Vandak 2007).

Table 3. Phycoerythrin (%) yield in *Arthrospira* dry biomass at 8 days after inoculation

Single influence of pH (P)	Single influence of salinity (S) (LSD _{0.05} = 0.194)				Main influence of pH (P) (LSD _{0.05} = 0.096)
	S1	S2	S3	S4	
P1	7.361*	8.783*	8.442*	8.367*	8.623*

P3	82.849**	81.143*	84.950**	84.811**	83.862*
Main influence of Salinity (S) (LSD _{0.05} = 0.345)	82.391*	83.856*	84.712*	82.601*	

The mechanism for removing nitrogen in water is determined by several factors, including bacterial activity (Gardner et al. 1986), uptake by plants (Bost 1990), and sorption (Boscher-Morel et al. 2001). In Cyanobacteria, nitrogen is a macromolecule that plays an important role in the formation of biochemical compounds such as nucleic acids (DNA, RNA), amino acids (protein), and pigments (chlorophyll and phycoerythrin) (Markou et al. 2014). The results of the LSD_{0.05} on the main pH factor showed that the reduction in total nitrogen content in *Arthrospira* culture media in treatment P2 was significantly higher than in treatments P1 and P3. This is due to the higher density of *Arthrospira* in treatment P2 compared to other treatments, so that the utilization of nitrogen by *Arthrospira* in culture media is greater than in others. Markou et al. (2014) showed that the higher density of *Arthrospira* could be higher the absorption of nutrients including nitrogen.

The value of reducing total nitrogen content in S3 treatment was significantly higher than for other treatments. This showed that treatment S3 caused *Arthrospira* to absorb nitrogen higher than other treatments in line with the high density and treatment of phycoerythrin *Arthrospira* obtained in this study. Jabon and Ahmad (2013) showed that salinity in culture media influences nitrogen absorption and protein biosynthesis. Reduction of total nitrogen content in *Arthrospira* culture media due to interactions between pH and salinity factors showed that treatment P2S3 was significantly higher than other treatments. With the optimal conditions (pH and salinity), *Arthrospira* is able to make maximum use of nitrogen. This can be seen from the higher density, growth rate and treatment of phycoerythrin found in treatment P2S3. The amount of nitrate and phosphate decreases with increasing growth of *Chlorella vulgaris* and *Arthrospira platensis* (Syaiful et al. 2016). This is because algae have the ability to absorb nutrients such as nitrogen and phosphate are used to carry out photosynthesis and protein production.

Reduction of phosphorus content in water is influenced by the process of absorption, complexation, deposition and assimilation (between microbes and plant biomass) (Tanner et al. 1999).

The results of LSD_{0.05} on the main factor of pH showed that each treatment did not significantly affect the reduction of phosphate content in *Arthrospira* culture media. Plants can only absorb phosphorus in the form of H₂PO₄ and HPO₄²⁻ but orthophosphate ions (Becker et al. 2014). The orthophosphate content decreases with increasing media pH. Corral and Fitzsimons (2016) showed the orthophosphate content increases in the pH range from 3.5 to 8.5 and decreases when pH 10. The fall in the orthophosphate content at pH 10 is due to an increase in calcium phosphate formation. The value of reducing the phosphate content in *Arthrospira* culture media was presented in Table 5.

The salinity factor, administration of different salinity in each treatment has no significant effect on reducing the phosphate content. Basim et al. (2011) explained the reduction of phosphorus will be inhibited when a combination of Cl⁻ and nitrite and Cl⁻ concentration more than 2.5 g L⁻¹. The interaction effect of differences in pH and salinity, each treatment had no significant effect on reducing phosphate content. Hing et al. (1995) showed that the utilization of Dissolved Organic Phosphorus (DOP) can be through active uptake into cells or by extracellular mineralization by phosphorus enzymes. However, most DOP compounds cannot be assimilated directly with microalgae because they have been mineralized. Markou et al. (2014) stated that phosphorus is a macromolecule that plays an important role in the preparation of nucleic acids (RNA and DNA), phospholipids and energy-carrying molecules (ATP). The phosphorus content in plants is lower than Ca, N, and K (Sasag et al. 2018). Although the analysis of variance shows that the results are not significantly different, but the highest phosphate reduction still occurred in treatment P2S3.

Mismatch of pH will cause loss and ion change the shape of pigment growth (Harjoto 2004). The process of photosynthesis affects pH value. In daylight aquatic plants release carbon dioxide from water for use in photosynthesis. The release of carbon dioxide by plants occurs through respiration. When carbon dioxide is released, carbonic acids build up and hydrolyzed so that the pH of the water will increase (Beal 1990, Prasad 2018) showed that growth of *Arthrospira* could be inhibited if it was in the pH range above 10.5 or less than 7. Salinity is one of the factors that can influence osmotic pressure for *Arthrospira* as the status of osmolyte. Paul and Laha (2001) microalgae can experience cell shrinkage in conditions outside the cell salinity higher than inside the cell (hypertonic), and vice versa under conditions of low salinity outside the cell (hypotonic) cell swelling will occur due to water molecules outside move into the cell. This condition affects the process of photosynthesis, and makes osmolyte to produce secondary metabolites in the form of β-carotene to sustain life against changes in salinity in culture media. While in osmotic conditions, cell fluid is osmotic to its external media which causes low active ion transport and membrane exchange, making the Na-K-ATPase enzyme activity at a maximum level and more energy will be utilized for growth (Rahmawati et al. 2013). The optimal combination of pH and salinity causes the growth of *Arthrospira* to be maximal. The optimal salinity range for *Arthrospira* is between 15-25 ‰, from the related research showed that the results of *Arthrospira* culture with 20 ‰ of media salinity, pH 7.3-8.5 using fertilizer media (0.010 g L⁻¹ TSP, 0.036 g L⁻¹ Urea, and 0.030 g L⁻¹ ZA) and a culture period of 5 days produced a dry weight of *Arthrospira* of 0.0375 g L⁻¹ (Prasad 2018).

Recovery of phycoerythrin

The recovery of phycoerythrin was presented in Table 3. The pH condition of maintenance media can affect protein content in *Arthrospira* cells. The results of LSD_{0.05} on the main factor of pH showed that the maximum of phycoerythrin *Arthrospira* in treatment P2 was significantly higher compared to other treatments. Taufiqurrahmi et al. (2017), the amount of *Arthrospira* biomass influences the high amount of phycoerythrin. Table 3 showed that the highest of *Arthrospira* biomass was found in treatment P2. It showed that the highest *Arthrospira* biomass produced the highest recovery of phycoerythrin (Table 3). The culture medium of *Arthrospira* pH of 8.5 produced the highest phycoerythrin content (Harjoto et al. 2016). Rahmawati et al. (2013) said that the higher C-phycoerythrin followed the higher of recovery of phycoerythrin.

LSD_{0.05} showed that the main factor of salinity showed the reduction of phycoerythrin in treatment S3 (salinity of 20 ‰) was significantly higher than other treatments. It is thought that the difference in salinity treatment has an impact on the external osmotic pressure of *Arthrospira* which results in changes in cell composition especially phycoerythrin. Solutes will flow into the cell and cause the release of phycoerythrin (phycoerythrin,

phycoerythrin and allophycocyanin) from PS II (Photosystem II) and stop the electron transporting to PS I (Photosystem I) followed by activation of the protective mechanism *Arthrospira* will produce carbohydrates to balance intracellular osmotic pressure and require more energy to remove sodium ions from cells. In this case it will produce osmolyte assimilation causes inhibition of protein synthesis (Zhou et al. 2017).

The environment includes the availability of osmotic, pH, salinity, light and temperature can affect the growth and accumulation of phycoerythrin from microalgae (Stern and Tsvetkov 2014). The condition of culture media is able to influence the growth phase of *Arthrospira*, causing changes in the composition and proportion of phycoerythrin (phycoerythrin, phycoerythrin and allophycocyanin) (Stern et al. 2013). The results of the LSD_{0.05} was showed that the maximum of phycoerythrin *Arthrospira* on the interaction between factors in treatment P2S3 was significantly higher than in other treatments, but it was not significantly different from treatment P2S2. This showed the density and growth rate of *Arthrospira*. The increasing salinity will cause maintenance media to be hypertonic towards cells and results in poor absorption of nutrients by cells. These cells could reduce protein and increase in carbohydrates from *Arthrospira* cells (Rahmawati et al. 2013).

Production of phycoerythrin was able to reach 12.4% - 17.8% of biomass dry weight of *Arthrospira* cultured in Zarook, Madinah (ZM) (Patan et al. 2018, Garcia-Lopez et al. 2020). There are several factors that affect the maximum of phycoerythrin include temperature, nutrient type, nitrogen, biomass, type of solvent, and the ratio of biomass to the solvent (Taufiqurrahmi et al. 2016). The content of phycoerythrin in cyanobacteria increases when grown in low light intensity. Phycoerythrin is a pigment associated with protein, polar and water-soluble. The protein content of microalgae is influenced by environmental conditions such as temperature, age of culture, light intensity, pH, salinity, and nutrient limits (especially nitrogen). Nitrogen is an essential element needed for the synthesis of accessory pigments and chlorophyll. When microalgae are growing fast, it requires large amounts of nitrogen and cold-temperature phycoerythrin as an alternative source of nitrogen for the production of biomass (Heick-Lo et al. 2019). It must be optimized for biomass production and phycoerythrin content. The higher concentration of phycoerythrin will be followed by the maximum of phycoerythrin. In this study, the phycoerythrin content is lower than previous study, because of different media for culturing *Arthrospira*. The source from ZM (geo analysis reference) is more complete for growing and farming phycoerythrin than maintenance earth pond media, especially the trace mineral in ZM.

Reduction of total nitrogen and phosphate content

The percentage reduction of total nitrogen in the culture media was presented in Table 4.

Table 5. Reduction of phosphate content in *Arthrospira* culture media (%)

Single influence of pH (P)	Single influence of salinity (S) (LSD _{0.05} = 0.096)				Main influence of pH (P) (LSD _{0.05} = 0.096)
	S1	S2	S3	S4	
P1	70.580	71.467	73.000	72.333	71.875
P2	74.667	74.800	74.667	72.667	74.000
P3	76.333	76.333	74.667	72.667	71.333
Main influence of salinity (S)	71.833	72.800	73.778	72.333	

**Figure 4.** Morphology of *Arthrospira* in earth wastewater culture media at several treatments of pH and salinity

Morphology of *Arthrospira* in various pH and salinity media

Morphology of *Arthrospira* was affected by increasing or decreasing physical or chemical factors in their culture media. Salinity and acidity value combination in this study didn't change the filament of *Arthrospira* significantly as their filament of *Arthrospira* under microscope with 100x magnification (Figure 4). The morphological forms of *Arthrospira* were not different in all pH and salinity treatments. The wastewater earth pond media could be affected in the branching filament. This study indicated

that salinity and acidity of culture media didn't affect various forms of filament, either straight and helical.

The straight filaments were observed for *Arthrospira* strain during two years of cultivation, and their presence in *Arthrospira* sp. Nigrita C1 cultures was constant. The various morphological plasticity, greatly influenced by their growth stage and environmental parameters, such as temperature and light intensity, was observed for *Arthrospira* strain (Pappasopoulos and Gleris 2019). There are indications that adaptability to change in environmental conditions is relatively rapid and also

subsequent changes at the genetic level can be realized quickly. This means that we can easily find different genotypes in various stable, ecologically different habitats. Morphologically similar strains were cultured for a long time under uniform and stable conditions (Komarek 2016). But the morphological changes could not be effected by acidity and salinity of culture media.

In conclusion, *Arthrospira* that is cultured on waste media (observed in liquid culture) indicated some short and linear filaments. Identified *Arthrospira* had a genetic distance of 6.8% between AF and AW isolates. AF isolates had a close relationship with *Arthrospira platensis* peth species originating from Japan (bootstrap value of 95%) while AW isolates form phylogenetic branches which are separated from AF isolates and *Arthrospira platensis* peth species originating from Japan (bootstrap value 85%). The catfish culture wastewater media at different pH and salinity affects the density, growth rate, and rendement of phycocyanin *Arthrospira platensis*. The highest density, growth rate and rendement of phycocyanin were in P2S3 treatment (pH 8.5 ± 0.2 and salinity of 20 ‰) which produced a maximum density of 0.867 g L^{-1} , growth rate of $22.026\% \text{ day}^{-1}$ and the rendement of phycocyanin of 11.334 %.

ACKNOWLEDGEMENTS

We thank staff at Aquaculture Laboratory and Plant Physiology Laboratory, Faculty of Agriculture, Sriwijaya University, Indonesia. The authors also acknowledge the contribution of the Sriwijaya University for Profession Research Grant (No. 0144.25/UN9/SB3.LP2M.PT/2019).
