# Abstracts

- 108 Effects on Lipid Metabolism and Endothelial Function of Hormone Replacement Therapy with 0.625Mg Cee Combined with Sequential 10Mg Dydrogesterone in Postmenopausal Women – **Shinohara, Koichi**
- 109 Menopause, The Most Beautiful Period In The Life Of A Woman – **Siregar, Muhammad Fidel Ganis**
- 109 The Association of Carotid Artery Intima-Media Thickness and Lipid Profile, Blood Pressure, and Atherosclerosis-Related Factors in Post Menopausal Japanese Women – **Somekawa, Yoshiaki**
- 110 BMD Changes After Hormone Therapy on Turner Syndrome – **Song, Jae Yen**
- 110 The Effect of 2-year Bi-weekly Administration of Alendronate on Bone Mineral Density and Bone Turnover Marker in Postmenopausal Korean Women Compared with Once-weekly Administration – **Suk-Joon, Chang**
- 111 A Comparison of the Effect of Bisphosphonates on Bone Mineral Density in Postmenopausal Korean Women with Osteoporosis – **Sung, Eun Hur**
- 111 Genistein Prevent Apoptosis Through Increase Expression of eNOS, BCL2 and Camp (Study in Oxydative Stress Human Endothelial Cells Culture) – **Suparman, Sutrisno**
- 112 Effect of Geristein on Differentiation of Human Subcutaneous and Visceral Preadipocyte – **Tak, Kim**
- 112 Background Factors that Affect Supplement Consumption in Japanese Women with Climacteric Symptoms – **Takamatsu, Kiyoshi**
- 113 Hypercholesterolemia Accelerates Bone Loss in Postmenopausal Women – **Tarakida, Ayako**
- 113 The Effect of Antimuscarinic Agent and Topical Estrogen in Postmenopausal Women with Overactive Bladder – **Temtanakitpaisan, Teerayut**
- 114 Natural S-Equol Supplement Relieves Menopausal Symptoms. A Randomized Placebo – Controlled Trial in Japanese Postmenopausal Women – **Uchiyama, Shigeto**
- 114 A Pilot Study to Finding the Effective Dose of Natural S-Equol Supplement for Relieving Menopausal Symptoms in Japanese Postmenopausal Women – **Ueno, Tomomi**
- 115 Perceptions of Menopause in Younger Women With and Without Breast Cancer – **Vincent, Amanda**
- 115 Androgen Receptor-Mediated Actions in Regulating Follicle Reserves and Development – **Walters, Kirsty**
- 116 Comparison of Bone Mineral Density Among the Postmenopausal Women of a Fishing Village and a Mountain Village in Korea – **Won Jun, Choi**
- 116 Different Effects of Oral and Transdermal Estrogen Therapy on Circulating Cytokines in Postmenopausal Women with Hysterectomy – **Yasui, Toshiyuki**
- 117 Relationship of Obesity and Bone Turnover Markers in Postmenopausal Women – **Yong, Il Ji**
- 117 Determination of an Applicable FRAX Model in Korean Women – **Yoon, Byung-Koo**
- 118 Analysis of C43g Mutation in the Promoter Region of the Xist Gene in Patients with Idiopathic Premature Ovarian Failure – **Yoon, Sang Ho**
- 118 Relationship Between Metabolic Syndrome and Bone Mineral Density in the Postmenopausal Women – **Young, Oak You**
- 119 Relationship Between Serum Leptin Level and Metabolic Syndrome in Postmenopausal Women – **Young, Oak You**
- 119 Characteristics of Chinese Women During Menopausal Transition – **Yu, Qi**

## The Role of Leptin on Estradiol and Bone Mass Density of Post-Menopausal Women

Ratsmawan, H.S<sup>1</sup>, Hendarto, H<sup>1</sup>, Darmosoekarto, S<sup>1</sup>, Soetomo, Dr<sup>1</sup>

<sup>1</sup>Dept. of Obstetric & Gynecology, Teaching Hospital, Surabaya, Indonesia

**Background:** Leptin is hormone with diverse range of local and systemic physiological functions produced in adipose tissues and secreted into the peripheral blood and also correlates well with body weight and adiposity. Estradiol has effects on food intake and body weight that are in the same direction as leptin. Serum estradiol also has positively correlation to bone density.

**Objective:** To evaluate whether leptin had role on estradiol and the bone mass density in postmenopausal women.

**Methods:** Serum leptin and estradiol of 17 non obese postmenopausal women and 17 non-obese nonmenopausal women as a control were evaluated using ELISA technique. Bone mass density value was evaluated using Dual energy X-ray absorptiometry (DEXA). All women had not taken any hormone, calcium and corticosteroid medication at least 6 months before the study. They had no established endocrinologic diseases (e.g. Hyperthyroidism, Cushing's disease, diabetes mellitus) or rheumatologic pathologies (e.g. rheumatoid arthritis, ankylosing spondylitis),

**Results:** Serum leptin concentration was higher in postmenopausal women ( $18,41 \pm 16,61$ ) compared with nonmenopausal women ( $9,27 \pm 3,01$ ) ( $p=0.02$ ). BMD in postmenopausal women was lower ( $1,00 \pm 0,16$ ) than nonmenopausal women ( $1,13 \pm 0,12$ ) ( $p=0.002$ ). The median concentration of estradiol in postmenopausal women was lower ( $<20$ ) than menopausal women ( $27,70$ ) ( $p=0.0008$ ). There were no significant correlations between leptin and estradiol concentration ( $r = 0.241$ ,  $p = 0.352$ ), and also between leptin concentration and bone mass density in postmenopausal women ( $r=0.625$ ,  $p=0.004$ ).

**Conclusion:** The increase concentration of serum leptin has no correlation on estradiol and bone mass density in postmenopausal women.

## Differences Effects of Isoflavone and Placebo in Reducing Hot Flushes Menopausal Women In Palembang

Rizani, Amran<sup>1</sup>, Yusuf, Effendi<sup>1</sup>, Suhair, Abadi A<sup>1</sup>

<sup>1</sup>Obstetrics and Gynaecology Department of Mohammad Hoesin Hospital Medical Faculty of Sriwijaya University.

**Background:** Hot flushes is the most vasomotor symptoms suffered by most women at age of menopause. Around three quarters of menopausal women experience symptoms of hot flushes in her life. These symptoms usually appear 1-2 years before menopause and will continue for six months until the next five years. Hot flushes in menopausal women will affect the ability to work, disrupt the social life, sleep pattern and daily activities. Effort to reduce symptoms for menopausal women is by giving hormone therapy; administration of estrogen with or without progestin, or selective estrogen receptor modulators (SERMs) such as raloxifene and tamoxifen. Besides that, hormone therapy should also be done in the long term even for life so that it will cause the problems in compliance of drug using and higher costs. One of the most widely studied phytoestrogens are isoflavones, a 17-oestradiol which are weak estrogens and SERMs natural. Isoflavones are widely used derived from soy isoflavone extract in capsules, tablets and liquids.

**Objective:** Study aims to know the differences effect of isoflavones and placebo in reducing hot flushes complaints of menopausal women. Overall benefits of the research is expected Isoflavones to be considered as alternative therapy in managements of menopausal complaints and can improve quality of life of women during this period with relatively affordable cost.

**Design and method:** This study is randomized clinical trial to isoflavon 2x40mg group and placebo group during 12 weeks. Was performed from September 2007 until June 2008 at Muhammad Hoesin Hospital Palembang, Dempo Public Health Centre, and Merdeka Public Health Centre Palembang. There were 90 sample in age 45-55 years old that meet the inclusion criteria and participated to this study.

**Results:** From the results, the mean age of subjects in the isoflavone group for  $50,75 \pm 2,31$  years old and  $51,10 \pm 2,25$  years old in placebo group. The mean menopausal age of isoflavone group for  $48,12 \pm 1,57$  years old and  $48,30 \pm 1,53$  years old in placebo group. The majority of subject had a normal body mass index (BMI= 18,5-25), as many as 30 subject (75,0%) in isoflavon group and 28 subject (70%) in placebo group. The biggest subject distribution of isoflavon group is more than 2 parity as many as 29 subject (72,5%), likewise in placebo group 23 subject (67,5%). Overall, subject characteristics of both group before intervention was found on the entire body of 18 subjects (45,0%) in the isoflavon group and 16 subjects (40%) in placebo group.

**Conclusions:** Result showed there were significant differences in the effect of isoflavone and placebo in reducing hot flushes complaints of menopausal women. Frequency of hot flushes decrease significantly in the first two weeks up to two weeks of sixth. The mean frequency of hot flushes at two weeks of sixth is  $9.60 \pm 4.18$  times in two weeks ( $\pm$  once a day) in isoflavone group and  $17.98 \pm 5.51$  times in two weeks ( $\pm$  twice a day) in placebo group ( $P < 0.05$ )

This is also followed by a decrease in the duration and severity of hot flushes in the group of isoflavone. In the two weeks of sixth, the average duration of hot flushes isoflavone group  $2.20 \pm 1.01$  minutes versus  $5.70 \pm 3.03$  minutes in group placebo and have proven statistically significant. Overall in isoflavone group, there were 32 subjects with mild degrees of hot flushes and 8 subjects with moderate hot flushes. While in the placebo group, there were 17 subjects with mild degrees of hot flushes and 23 subjects with moderate degrees of hot flushes.

# DIFFERENCES EFFECT OF ISOFLAVON AND PLACEBO IN REDUCING HOT FLASHES MENOPAUSAL WOMEN IN PALEMBANG

Rizani Amran, Yusuf Effendi, Suhair, Abadi A

*Department of Obstetrics and Gynecology  
Faculty of Medicine Sriwijaya University/ dr. Muhammad Hoesin Hospital  
Palembang*

**Background:** The purpose of this study was to find the differences between the effect of isoflavon and placebo in reducing the hot flashes in menopausal women.

**Settings:** This study was conducted in Mohammad Hoesin Hospital Palembang, Dempo Public Health Service, and Merdeka Public Health Service Palembang.

**Design:** This a randomized control trial. The evaluation of hot flashes was based on the Hot Flashes Score from Sloan.

**Methods :** This study was conducted from September 2007 until June 2008. During this period total sample that matched with the inclusion criteria was 90 subjects, aged from 45-55 years. We also evaluated the FSH level.

We divided the subject using simple randomization with numbered random table. We found 44 subjects in isoflavon group, 43 subjects in placebo group. During the study period, there were 4 subjects from isoflavon group and 3 subjects from

placebo group dropped out from the study because they did not take the medication or lost of follow up.

**Results:** Mean age of the study sample from isoflavon group was  $50,75 \pm 2,31$  years, and placebo group was  $51,10 \pm 2,25$  year. There are significant decreasing in the first two weeks until the sixth two weeks. Mean frequency in the sixth two weeks was  $9,60 \pm 4,18$  times in two weeks or  $\pm 1$  time daily in the isoflavon group, and  $17,98 \pm 5,51$  times in two weeks or  $\pm 2$  times daily in placebo group ( $p < 0,05$ ). This is followed by the decreasing of the hot flashes duration in isoflavon group. In the sixth two weeks, the mean duration of hot flashes in isoflavon group was  $2,20 \pm 1,01$  minutes, and  $5,70 \pm 3,01$  minutes in placebo group, and statistically significant ( $p < 0,05$ ).

**Conclusion:** It was statistically proven using the  $\chi^2$  test that there are no differences in hot flashes duration between isoflavon and placebo group ( $p = 0,822$ ).

**Keywords:** Hot flashes, isoflavon, menopause.

## Introduction

Menopause was defined as a period when the menstrual cycle was stop, followed by the lost follicle activity.<sup>2,5</sup> Menopause derived from the Greece word "men" (month) and "pausis" (stop). Few years before the menopause happened, there are changes in normal ovarian cycle until the cycle was stop, this is called menopause

transition, where the cycle is not normal.

The symptoms include changes in menstrual pattern, vasomotor symptoms (hot flashes, sweating), genital atrophy, and secondary problems that was caused by the lack of estrogen, such as osteoporosis and cardiovascular disease.<sup>4,5</sup>

Hot flashes are the main vasomotor symptoms in menopausal women. 1/3 of

menopausal women experiencing hot flashes during their menopausal period. This symptom happens 1-2 years before menopause and continued until 6 months – 5 years later.<sup>6,7</sup>

According to Kronenberg, in 20% of women, hot flashes will occur until 15 years after menopause.<sup>8</sup> This symptom will affect the ability to work, disturbed social life, and daily activity.

There were several ways to reduce this symptom, include hormonal therapy, estrogen therapy with or without progestin or selective estrogen receptor modulators (SERMs) such as raloxifene and tamoxifene.<sup>9,10</sup> But this hormone replacing therapy were also associated with the increased risk for breast cancer, coronary heart disease, cerebrovascular disease, and lung embolism. Another problem in hormone replacing therapy is that before we begin the therapy, we have to perform the screening test, and this therapy needs long terms follow up. This therapy is should be given in long term. This therapy is also need the adherence and high cost therapy.<sup>11</sup>

One of the efforts to solve this problem is to develop the preparat such as natural estrogen therapy like fitoestrogen.<sup>12-14</sup>

One of the fitoestrogen that have been studied is isoflavon, 17 $\beta$ -oestradiol which is the week estrogen and natural SERM. Isoflavon that have been used recently derived from soya, in the shape of capsul, tablet, and liquid.<sup>15</sup> Research from Kyung K, Han and Jose M. Soarces from Brazil in 80 menopausal women with hot flashes symptom, showed that 100 mg isoflavon administration will reduce this symptom significantly ( $p < 0,01$ ) after 12 weeks.<sup>16</sup> Another research showed a different result, Kronenberg and Fugh-Berman make a study to 29 randomized clinical trial about alternative therapy in menopausal symptom, showed that there is no consistent prove about the benefit of alternative therapy

although 6 from 11 randomized control trial using isoflavon showed changes in hot flashes symptom and menopausal symptom.<sup>8</sup> This study was a meta analysis study which is different from Kyung K, Han and Jose, so this study showed a different result.

There differences between this result makes us interested to performed the clinical trial on the effect of isoflavon in reducing hot flashes symptom in menopausal women in Palembang.

## Material and methods

This is a randomized control trial to the group that was given 2x40 mg isoflavon and placebo for 12 weeks. All of the participants were given daily journal about the degree of hot flashes that were evaluated in 4<sup>th</sup>, 8<sup>th</sup>, and 12<sup>th</sup> weeks. The evaluation of hot flashes was based on the Hot Flashes Score from Sloan.

## Study population

Study population are the menopausal women in Palembang that matched the inclusion criteria. Material of the study are women in Mohammad Hoesin Hospital, Merdeka Public Health Service, Dempo Public Health Service who were matched the inclusion criteria.

## Study Sample

Sample were collected from September 2007. Sample size had 95% confidence interval, and power test 80%. The result that was expected 12 weeks after the isoflavon treatment is 80%. Sample size in this study were based on the formula:

$$n = \frac{Pt(1 - Pt) + Pc(1 - Pc)}{(Pt - Pc)^2} \times f_{(\alpha, \beta)}$$

where:

$n$  = number of sample

$Pt$  = proportion that was expected 80%

$Pc$  = placebo proportion 50%

f = coefficient from the table with  $\alpha$  95%,  $\beta$  80% is 7,9

$\alpha$  = confident interval 95%

$\beta$  = power test 80%

$$n = \frac{0,8(1 - 0,8) + 0,5(1 - 0,5)}{(0,8 - 0,5)^2} \times 7,9$$

= 35,9 sample  $\rightarrow$  36 sampel.

Minimum sample size from each group were 36 sample, in this study we found 40 sample that participate until the study finished.

#### **Inclusion criteria**

- Menopausal women who did not had menstruation in 12 weeks.
- Hot flashes symptom.
- FSH serum more than 40 mIU/ml.
- Agree to participate and sign the informed consent form.

#### **Exclusion criteria**

- Using the hormonal drug or other therapy for systemic disease (DM, hypertension, hormone replacing therapy)
- History of hysterectomy and or salphingooforectomy
- Withdrawl from the study.

#### **Study variable**

Study variable include:

- Demography characteristics
- Frequency of hot flashes
- Duration of hot flashes
- Degree of hot flashes

#### **Tools and materials**

Tools and material in this study consist of:

- Isoflavon capsule isoflavon 40 mg (Promeno®)
- Placebo capsule contained glycerin
- Dispossible syringe 3 cc
- Double oxalat tube
- Daily form

#### **Working procedure**

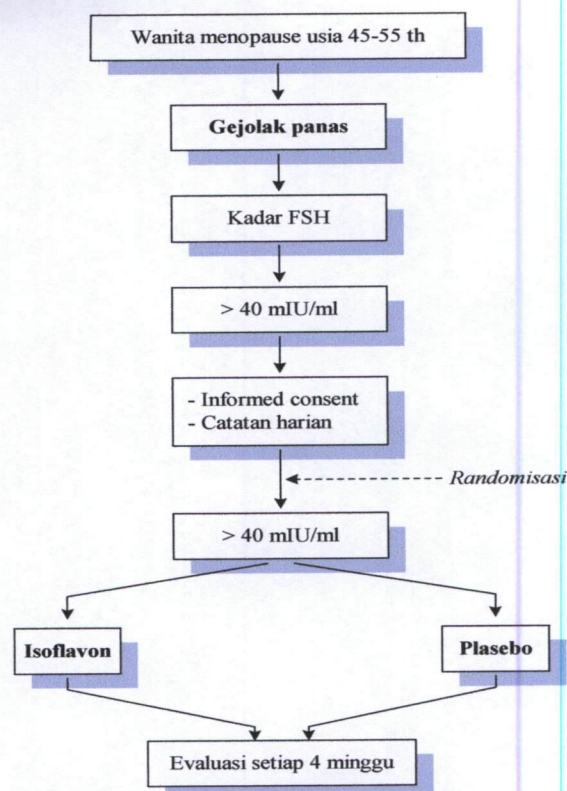

Women who were matched the inclusion criteria, were given the number based on the alphabet. Performed the simple randomization using the numbered random table, then we performed the anamnese to the responden. If the responden agree to participate in the study then they sign the informed consent.

After that we check the FSH serum by collecting 5 cc of blood sample from vein. Then the blood samples were collect in the tube and given the label name and send to the Prodia Laboratory in Palembang. Then the respondents were given the information about how to fill the questioner for daily forms that were given to the respondent. The respondents will be given the placebo or isoflavon for 4 weeks and every day they took the medication at 07.00 AM and 07.00 PM. And the medication was continued for the next 8 weeks.

The capsule usage was controlled by called the respondents, visited the respondents house, and confirmed at the second and third week of capsule administration. During the confirmation, we performed the evaluation of daily journal, and the respondents were remain about the procedure of the medication and to fill the daily journal every day.

Evaluation of the side effects and the problems that were happened during the study, such as if the respondents were sick, the usage of other medication and antibiotic during the study should be written in special card and should be reported to the researcher for further evaluation.

### Statistical Analyses

Study data were collected in a form that were analysed using the software SPSS version 11 Windows. Statistical analysis were conducted using the Mann-Whitney test for both group, and we performed the Wilcoxon test to analyse the differences of median data for isoflavon group in the observation 0 (P0), 4<sup>th</sup> weeks (P1), 8<sup>th</sup> weeks (P2), and 12<sup>th</sup> weeks (P3). The significance was based on the  $p$  value  $< 0,05$ .

### Results

#### Subjects Characteristics

The mean age for isoflavon subjects were  $50,75 \pm 2,31$  years, in placebo group  $51,10 \pm 2,25$  years. The subjects were mostly in the age of 51–55 years that were consist of 23 isoflavon subjects (57,5%), and 27 subjects (67,5%) in placebo group. The educational degree in most of the subjects were university/ diploma 20 subjects (50,0%), and 23 subjects (57,5%) in placebo group. 5 isoflavon subjects were elementary school

(12,5%), and 4 placebo group. Both the majority of group sample were a working women, which is consist of 23 subjects (57,5%) and 27 subjects (67,5%).

Most of the subjects in isoflavon group (30 subjects/ 75,0%) had the body mass index (BMI) 18,5 – 25 (normal), and 28 subjects (70,0%) in the placebo group. Only 4 subjects (10,0%) in isoflavon group and 1 subjects (2,5%) in placebo group had BMI  $< 18,5$ . There are 6 subjects (13,4%) in isoflavon group and 11 subjects (27,5%) in placebo group had the BMI  $> 25$ .

Most of the isoflavon subjects had 3 parity (18 subjects/45,0%), and in placebo group most of the subjects had 2 parity (13 subjects/ 32,5%). In isoflavon group there are 1 subject (2,5%) that had 7 parity, and 2 subjects (5,0%) in placebo group. The characteristics of the subjects are shows in table 4.

Table 4. Distribution of the subjects based on the age, education, BMI, parity.

| Characteristics       | Isoflavon |       | Placebo |       |
|-----------------------|-----------|-------|---------|-------|
|                       | n         | %     | n       | %     |

### Comparison Analysis

#### Subjects General Characteristis

Analysis of the subject characteristics is to find the homogeneity in both group. According to the age, we found the analysis result using the  $\chi^2$ , there are no significant differences between both group ( $p=0.356$ ). The result of this analysis is shows in Table 5.

Table 5. Comparison analysis of subjects' age

| Age (year) | Isoflavon |       | Plasebo |       |
|------------|-----------|-------|---------|-------|
|            | n         | %     | n       | %     |
| 45-50      | 17        | 42,5  | 13      | 32,5  |
| 51-55      | 23        | 57,5  | 27      | 67,5  |
| Total      | 40        | 100,0 | 40      | 100,0 |

$\chi^2$  test;  $p=0,356$

The education of the subjects were divided into low education (below senior high) and high education (above senior high). The analysis using  $\chi^2$  test shows that there are no significant differences between both group ( $p=0.501$ ). Result from this analysis is shows in Table 6.

Table 6. Comparison analysis of the subject's education

| Education     | Isoflavon |       | Plasebo |       |
|---------------|-----------|-------|---------|-------|
|               | n         | %     | n       | %     |
| ≤ High School | 20        | 50,0  | 17      | 42,5  |
| > High School | 20        | 50,0  | 23      | 57,5  |
| Total         | 40        | 100,0 | 40      | 100,0 |

$\chi^2$  test;  $p=0,501$

The occupation of the subjects in both group were divided into house wife and working women. From the analysis using  $\chi^2$ , there are no significant differences between both group ( $p=0,356$ ), shows in table 7. Table 7. Comparison analysis of subjects occupation

| Occupation | Isoflavon |       | Plasebo |       |
|------------|-----------|-------|---------|-------|
|            | n         | %     | n       | %     |
| Housewife  | 17        | 42,5  | 13      | 32,5  |
| Working    | 23        | 57,5  | 27      | 67,5  |
| Total      | 40        | 100,0 | 40      | 100,0 |

$\chi^2$  test;  $p=0,356$

There are no significant differences in body mass index in both group ( $p=0.188$ ), shows in table 8.

Table 8. Comparison analysis for BMI

| BMI       | Isoflavon |       | Placebo |       |
|-----------|-----------|-------|---------|-------|
|           | n         | %     | n       | %     |
| < 18,5    | 4         | 10,0  | 1       | 2,5   |

### Menstrual characteristics analysis

In this study we performed the analysis for the menstrual history, consist of menarche, menopause, menstrual duration in one cycle, and the duration when the patient stop menstrual. We found the mean menarche age  $13,03 \pm 1,34$  years in isoflavon group, and  $12,88 \pm 1,45$  years in placebo group. Mean menopause age for isoflavon group  $48,12 \pm 1,57$  years, and  $48,30 \pm 1,53$  years in placebo group. Mean menstrual duration in isoflavon group  $5,08 \pm 1,24$  days, and  $5,30 \pm 1,20$  in placebo group. The mean duration for non menstrual period was

$31,5 \pm 15,53$  months and  $33,6 \pm 16,3$  months in placebo group.

Overall using the t test, we found there are no significant differences in menarche age, menopause age, menstrual duration, non menstrual period between both group. ( $p>0.05$ ). The analysis result for the menstruation history shown in table 10.

Table 10. Comparison analysis for menstruation history

| Variable                             | Isoflavon<br>(mean $\pm$ SD) |       | Placebo<br>(mean $\pm$ SD) |      | p     |

t test ; SD: standard deviation

### Analysis of the history and location of hot flashes

#### 1. Duration of hot flashes

The duration of hot flashes before the treatment were divided into two group,  $\leq 2$  years, and  $> 2$  years. Most of the subjects felt the hot flashes for more than two years, 22 subject in isoflavon group (55%) dan 23 subject (57,5%) in placebo group. The proportion of the hot flashes duration, shown in table 11.

Table 11. Comparison analysis of hot flashes

| Hot flashes<br>duration<br>(year) | Isoflavon |       | Placebo |       |
|-----------------------------------|-----------|-------|---------|-------|
|                                   | n         | %     | n       | %     |
| $\leq 2$                          | 18        | 45,0  | 17      | 42,5  |
| > 2                               | 22        | 55,0  | 23      | 57,5  |
| Total                             | 40        | 100,0 | 40      | 100,0 |

duration

$\chi^2$  test;  $p=0,822$

It was statistically proven using the  $\chi^2$  test that there are no differences in hot flashes duration between both group ( $p=0.822$ ).

## 2. Location of hot flashes

Characteristics of hot flashes location in this study divided into three groups in the face, neck, and the whole body. Before the intervention the location of hot flashes mostly in the whole body, 18 subjects (45,0%) in isoflavon group and 16 subjects (40%) in placebo group. Location of hot flashes for both group shown in table 12.

Table 12. Comparison analysis for hot flashes location

| Hot flashes location | Isoflavon |       | Placebo |       |
|----------------------|-----------|-------|---------|-------|
|                      | n         | %     | n       | %     |
| Face                 | 9         | 22,5  | 10      | 23,8  |
| Neck                 | 13        | 32,5  | 14      | 33,8  |
| Whole body           | 18        | 45,0  | 16      | 42,4  |
| Total                | 40        | 100,0 | 40      | 100,0 |

$\chi^2$  test;  $p=0,902$ .

Using  $\chi^2$  test, there are no differences in hot flashes location in both group ( $p=0.902$ ).

## The effect of isoflavon and placebo in reducing the hot flashes in menopausal women

### 1. Hot flashes frequency

The evaluation for the frequency of hot flashes was based on Hot Flashes Score from Sloan, and evaluate for two weeks. Mean hot flashes frequency before the intervention in isoflavon group were  $18,92 \pm 5,92$  times in two weeks or  $\pm 2$  times daily, and

$16,10 \pm 5,59$  times in two weeks or  $\pm 2$  times daily in placebo group.

In the first two weeks after the intervention there are decreasing of the hot flashes intervention in isoflavon group  $16,05 \pm 5,18$  times in two weeks or  $\pm 1,5$  times daily, and in placebo group there are increasing of frequency become  $20,60 \pm 6,25$  times in two weeks, or  $\pm 2$  times daily. Frequency of hot flashes shows in table 13.

Table 13. Frequency of hot flashes

| Hot flashes frequency per 2 weeks (14 days) | Isoflavon (mean $\pm$ SD) |      | Placebo (mean $\pm$ SD) |      | <i>p</i> |
|---|---------------------------|------|-------------------------|------|----------|
| 2 weeks before                              | 18,12 $\pm$               | 5,92 | 16,10 $\pm$             | 5,59 | 0,120    |
| I 2 weeks                                   | 16,05 $\pm$               | 5,18 | 20,60 $\pm$             | 6,25 | 0,001    |
| II 2 weeks                                  | 15,00 $\pm$               | 5,09 | 21,43 $\pm$             | 6,07 | 0,0001   |
| III 2 weeks                                 | 13,48 $\pm$               | 5,08 | 20,88 $\pm$             | 6,10 | 0,0001   |
| IV 2 weeks                                  | 11,50 $\pm$               | 4,70 | 18,63 $\pm$             | 5,95 | 0,0001   |
| V 2 weeks                                   | 9,75 $\pm$                | 4,63 | 18,55 $\pm$             | 5,96 | 0,0001   |
| VI 2 weeks                                  | 9,60 $\pm$                | 4,18 | 17,98 $\pm$             | 5,51 | 0,0001   |

t test ; SD = standard deviation

Within 2 weeks before the intervention we performed the t test, and we found there is no significant differences in hot flashes frequency between both group ( $p=0.120$ ). Within the first two weeks until the sixth two weeks after the intervention, we found significant differences in hot flashes frequency between two groups ( $p<0.05$ ).

The distribution of hot flashes frequency in this study shown in table 6. At the beginning of the study we found the frequency of hot flashes is higher in isoflavon group compared with placebo group. In the first two weeks there are decreasing of hot flashes frequency in isoflavon group, and increased in placebo group. In the second two weeks after the

intervention, there decreasing in hot flashes frequency in isoflavon group, but remains still in placebo group.

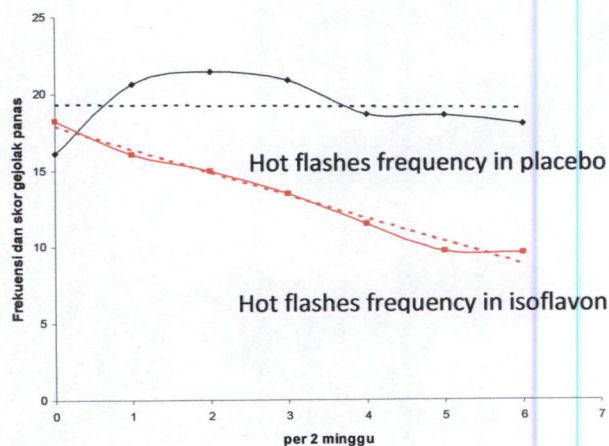

Figure 6. Frequency of hot flashes

## 2. Hot flashes duration

From this study we found the mean hot flashes duration before the intervention is  $5,13 \pm 3,45$  minutes in isoflavon group, and  $5,28 \pm 3,22$  minutes in placebo group. Duration of hot flashes in the first two weeks after the intervention, mean duration of hot flashes in isoflavon group is shorter  $3,63 \pm 2,57$  minutes, and  $5,08 \pm 2,28$  minutes in placebo group.

In the next two weeks, the duration in isoflavon group is shorter than the placebo group. Mean duration within the sixth two weeks is  $2,20 \pm 1,01$  minutes in isoflavon group and  $5,70 \pm 3,01$  minutes in placebo group.

There are no significant differences in the duration of hot flashes before the intervention between both group, but in the first two weeks until the sixth two weeks we found the significant t test ( $p < 0.05$ ). Duration of hot flashes shown in table 14.

Table 14. Analysis of hot flashes duration

| Duration of hot flashes (minute) | Isoflavon (mean $\pm$ SD) | Placebo (mean $\pm$ SD) | p      |
|----------------------------------|---------------------------|-------------------------|--------|
| 0 2 weeks                        | 5,13 $\pm$ 3,45           | 5,28 $\pm$ 3,22         | 0,842  |
| I 2 weeks                        | 3,63 $\pm$ 2,57           | 5,08 $\pm$ 2,28         | 0,005  |
| II 2 weeks                       | 3,88 $\pm$ 2,35           | 5,35 $\pm$ 2,40         | 0,007  |
| III 2 weeks                      | 3,28 $\pm$ 1,58           | 6,35 $\pm$ 3,22         | 0,0001 |
| IV 2 weeks                       | 2,83 $\pm$ 1,76           | 5,80 $\pm$ 3,09         | 0,0001 |
| V 2 weeks                        | 2,63 $\pm$ 1,59           | 6,15 $\pm$ 3,10         | 0,0001 |
| VI 2 weeks                       | 2,20 $\pm$ 1,01           | 5,70 $\pm$ 3,01         | 0,0001 |

t test ; SD = standard deviation

Distribution of hot flashes duration in both group shown in figure 7. At the beginning of the study, the hot flashes duration in isoflavon group is lower than placebo group, but not statistically significant ( $p=0.842$ ). In the first two weeks after the intervention, there are decreasing of hot flashes duration in isoflavon group, but not stable in placebo group. Within the next weeks we found there is decreasing of hot flashes in isoflavon group and increased in placebo group.

Figure 7. Duration of hot flashes

### 3. Hot flashes level

The evaluation of hot flashes in this study was based on the Hot Flashes Score from Sloan, and were divided into 4 category, consist of mild (1-14), moderate (15-28), severe (29-42), very heavy (43-56), shown in table 3. Table 15 shows the effect of the administration of isoflavon in reducing the hot flashes in menopausal women. Within two weeks before the administration of isoflavon and placebo, we found 17 subjects (42,5%) from isoflavon subjects with mild hot flashes, and 23 subjects (57,5%) with moderate hot flashes, mean while in placebo group we found 14 subject (35.0%) with mild hot flashes, and 26 subjects (65.0%) with moderate hot flashes.

In the first two weeks, in isoflavon group we found one subject that having changes in the level of hot flashes from moderate become mild, and in placebo group we found 5 subject from mild hot flashes become moderate. Overall there are 18 subjects (45%) with mild hot flashes and 22 subjects (55%) with moderate hot flashes. In placebo group, there are 9 subjects (22.5%) with mild hot flashes and 31 subjects (77.5%) with moderate hot flashes. Within two weeks after the administration, there are additional 2 subjects with moderate hot flashes become mild hot flashes, but remain the same in the placebo group.

In the third two weeks, the number of subjects in the isoflavon group, 8 subjects from moderate hot flashes become mild hot flashes, and in placebo group there are two subjects from moderate hot flashes become mild hot flashes. Overall, there are 25 subjects (62,5%) with mild hot flashes, and 15 subjects (37,5%) with moderate hot flashes in isoflavon group. But in placebo group there are 11 subjects (27,5%) with mild hot flashes and 29 subjects (72,5%) with moderate hot flashes.

It shows the same result in the fifth two weeks, there are decreasing in the subject with mild hot flashes in isoflavon group. In the fifth two weeks, in the isoflavon group there are 31 subjects (77,5%) with mild hot flashes, and 9 subjects (22,5%) with moderate hot flashes. But in placebo group, there are 15 subjects (37,5%) with mild hot flashes, and 25 subjects (62,5%) with moderate hot flashes.

From the beginning until the end of the study, in isoflavon group there are 15 subjects with moderate hot flashes become mild hot flashes, and in placebo group there are 3 subjects with moderate hot flashes become mild hot flashes. Overall in isoflavon group there are 32 subjects (80.0%) with mild hot flashes, and 8 subjects (20%) with moderate hot flashes. And in

placebo group, there are 17 subjects (42,5%) with mild hot flashes and 23 subjects (57,5%) with moderate hot flashes.

The result of the statistic analysis using t test shows, at two weeks before intervention there are no significant differences in the level of hot flashes between two group ( $p=0.001$ ). Mean while at the first two weeks until the sixth two weeks, we found significant differences between two group ( $p<0,05$ ). Level of hot flashes shown in Table 15.

Table 15. Level of hot flashes

| Level of hot flashes | Isoflavon |       | Plasebo |       | $p^*$ |
|----------------------|-----------|-------|---------|-------|-------|
|                      | n         | %     | n       | %     |       |
| 2 week 0             |           |       |         |       |       |
| Mild                 | 17        | 42,5  | 14      | 35,0  | 0,491 |

\*  $\chi^2$  test

## Conclusion

Mean age of the subjects was  $50,75 \pm 2,31$  years in isoflavon and  $51,10 \pm 2,25$  years in placebo group. Mean menopause age was  $48,12 \pm 1,57$  years in isoflavon and  $48,30 \pm 1,53$  years in placebo group. BMI in most subjects (30 subjects/ 75.0%) was 18,5–25 (normal), and 28 subjects (70.0%) in placebo group. Most of the isoflavon subjects had 2 parity, which is 29 subjects (72.5%), and in placebo group was 27

subjects (67.5%). Overall, there are no significant differences in the subjects characteristics between two groups ( $p>0.05$ ). The location of hot flashes between intervention mostly in the whole body, and we found it in 18 isoflavon subjects (45.0%) and 16 placebo subjects (40%).

Results of this study show that there are significant differences for the effect of isoflavon and placebo in reducing the hot flashes in menopausal women. There are significant decreasing in the first two weeks until the sixth two weeks. Mean frequency in the sixth two weeks was  $9,60 \pm 4,18$  times in two weeks or  $\pm 1$  time daily in the isoflavon group, and  $17,98 \pm 5,51$  times in two weeks or  $\pm 2$  times daily in placebo group ( $p<0,05$ ). This is followed by the decreasing of the hot flashes duration in isoflavon group. In the sixth two weeks, the mean duration of hot flashes in isoflavon group was  $2,20 \pm 1,01$  minutes, and  $5,70 \pm 3,01$  minutes in placebo group, and statistically significant ( $p<0.05$ ). Overall in isoflavon group there are 32 subjects (80.0%) with mild hot flashes and 8 subjects (20%) with moderate hot flashes. Mean while in placebo group there are 17 subjects (42.5%) with mild hot flashes and 23 subjects (57.5%) with moderate hot flashes.

The conclusion of this study is that, the administrasion of isoflavon could reduce the hot flashes, and this could be an alternative in symptomatic therapy in menopausal women.

## Recommendation

Isoflavon administrations were considered as the alternative therapy for the treatment of hot flashes in menopausal women, in order to increased the quality of life with the low cost therapy.
