Galley Proof - PDF No. 17

International Food Research Journal / UPM <ifrj@upm.edu.my> Thu, Feb 14, 2019 at 8:08 AM

Dear Dr. Santoso,
The Galley Proof of your manuscript is in the attached file.

To ensure accuracy of information in your manuscript, please check the PDF copy of the galley proof and please provide a list of correction(s) (if any, on a separate sheet of paper or on the PDF copy of the manuscript) that will help us to prepare the final copy of your manuscript for uploading onto the IFRJ website soon.

Unless we hear from you about this paper within 3 days of this email message, we will presume you have no further comments/corrections for your manuscript and thus giving us the confirmation to upload your manuscript. Once uploaded, further request for change(s) on your manuscript will not be entertain.

Note: The page numbers will be updated in the final copy.

Sincerely,
Norhafizah Mohamad Noh
Editorial Office

International Food Research Journal - Decision on Manuscript ID IFRJ17329.R2

International Food Research Journal <onbehalf@manuscriptcentral.com> Mon, May 14, 2018 at 1:26 PM

14-May-2018

Dear Dr. Nasir

Manuscript IFRJ17329 R2, entitled 'Protein Extract Addition of Paddy Field Eel in Processing of Edible Film from Modified Canna Starch', which you submitted to International Food Research Journal, has been reviewed again. The comments of the reviewers appear below.

Publication is recommended, subject to some further minor revision to your manuscript. Therefore, I invite you to respond to the comments below and proceed with revision.

Please download a copy of your manuscript from the system at STEP 6: File Upload after clicking 'CREATE REVISION' and use the file to do the revision. This is because the file has been edited according to the Journal's format.

Thank you for submitting your manuscript to International Food Research Journal. I look forward to receiving your revision. Instructions on how to revise your manuscript are included at the end of this letter.

Sincerely,
Prof. Chin Ping Tan
Editor, International Food Research Journal

line 81: natrium should be changed to sodium

in the introduction some text is written in italic, it is not clear why

as far as I can see, the graphs have not been changed as suggested.

HOW TO REVISE YOUR MANUSCRIPT

To revise your manuscript, log in to <https://mc.manuscriptcentral.com/upm-ifrj> and enter your Author Centre, where you will find this manuscript listed under 'Manuscripts with Decisions'. Under 'Actions', click on 'Create a Revision'.

You can also click the link below to start the revision process (or continue the process if you have already started your revision) for your manuscript. If you use the link below you will not be required to log in to ScholarOne Manuscripts.

*** PLEASE NOTE: This is a two-step process. After clicking on the link, you will be directed to a webpage to confirm. ***

https://mc.manuscriptcentral.com/upm-ifrj/20URL_MASK-93411a69542d4e1d838f4f128bead082

You will be unable to revise the files that you submitted for the original version of the manuscript. Instead, revise your manuscript using a word-processing program and save it on your computer. Once the revised manuscript is prepared, you can upload it and submit it through your Author Centre.

The effect of eel's protein extract on the characteristics of edible film from crosslinked modified canna starch

Abstract

This study aimed to study the effect of eel's protein extract on characteristics of modified Canna's starch edible film. Research method was addition of eel's protein extract at concentrations of 2%(v/v), 4%(v/v), and 6%(v/v) in the formulation of modified Canna's starch edible film. The observed parameters were percent elongation percentage, compressive strength, water vapor transmission rate and **microstructure**. The addition of eel's protein extracts increases the elongation percentage and decreases water vapor transmission rate of edible film. The edible compressive strength of the film decreases after the addition of eel's protein extract, but addition of higher concentration of eel's protein extracts had increased compressive strength of edible film.

Keywords: edible film, Canna's starch, eel's extract protein, modified, POCl_3

Introduction

The use of Canna's starch as raw material for edible film is still limited due to low values of elongation percentage, compressive strength and water vapor transmission rate. One of effort that can be done is by using modified Canna's starch through crosslinking of POCl_3 because the

Comment [W1]: There is no discussion of microstructure in the manuscript.

24 amylose and amylopectin compositions are relatively balance with
25 magnitude of 25% and 75%, respectively.

26 The use of modified starch is very important to produce edible film
27 matrix because POCl_3 compound creates a cross link between one
28 amylose chain to anothers through phosphate link. This phosphate link can
29 produce three dimension continous net and this net can trap water through
30 reactive OH which not bound with POCl_3 . The cross link of starch polymer
31 chains is occurred at groups containing more OH reactive, especially at OH
32 group numbers 2, 3 and 6 (Yoshida *et al.*, 2002). The numbers of reactive
33 OH group is affected by cross-linking degree and starch concentration.
34 Granulair size and ratio of amylose and amylopectin numbers of starch may
35 also affect the numbers of reactive OH group. The characterisics of these
36 starches may have effect on the producing of modified starch. According
37 toSantosoet *al.*(2011)the modified starch through cross linking by POCl_3
38 may produce good compressivestrengthbut low percent elongation and
39 water vapor transmission rate edible film. This low percent elongation and
40 water vapor transmission rate characteristics can be improve by the
41 addition of other compound such as glycerol and beeswax.

42 Glycerol and bees wax not only has positive effect, but also
43 negative effect such as increasing water vapor transmission rate
44 anddecreasing elongation degree of *edible film respectively*. The addition of
45 eel's extract protein is important to solve this problem. According
46 toArthamet *al.* (2008),fish protein based *edible film* which consisted or
47 myofibrillar protein or sarcoplasm generally have better mechanical

48 properties, especially in term of flexibility property. Nakai and Modler
49 (1999) had added that protein types of myofibrillar and sarcoplasmic are
50 found in abundant quantity on eels. Amino acid types and pH isoelectric
51 point also have profound effect on the edible film matrix (Prodpranet *al.*,
52 2007).Were *et al.* (1999)described that amino acids containing sulphur
53 have important role in edible film formation through disulfide bonding.
54 PoeloengasihandMarseno (2003) had added that in addition to disulfide
55 bonding, hydrogen bonding and hydrophobic interaction also determine
56 edible film properties, especially in term of amino acids having hydophobic
57 charateristic such as alanine, valine, leusin, triptophane and phenylalanine.

58 This research aimedtostudy theeffect of eel's
59 proteinextractoncharacteristics ofmodified Canna's starch ediblefilm and
60 eel' protein extract which in turn can improve elongation percentage,
61 compressive strength, and water vapour transmission rate of edible film.

62

63 **Material and method**

64 *Materials and equipments*

65 Material used in this study were canna's starch (white color) from
66 Pagaralam City, eel from Perumnas Market of Palembang. Eel is
67 processed into surimi to obtain protein extract. Chemicals used for
68 preliminary study were alcohol, distilate water, ether, HCl, NaOH, Fehling
69 solution, ethanol, methylene blue, iod solution, acetate acid, glycerol and
70 trisodium citrate having technical quality. Chemicals for production of
71 modified starch and edible film were natrium sulphate, POCl₃, glycerol,

Comment [W2]: acetic

Comment [W3]: technical grade

72 CMC, beeswax, pp indicator, HCl and ammonium molybdate. Equipments
73 used in this study were *hot plate*, *magnetic stirrer*, *vortex*, oven, desicator,
74 texture analyzer, testing Machine MPY (Type: PA-104-30, Ltd Tokyo,
75 Japan), and water vapor transmission rate tester Bergerlehr.

76

77 *Method*

78 *Modified Starch Processing from Canna's Starch with POCl₃ by Using Cross*
79 *Linking Method (Modified method of Wattanachantet et al., 2003)*

80 Procedure for modified starch processing with cross-linking method
81 by using multi functional reagent of POCl₃ is as follows: sodium sulphate
82 (Na₂SO₄) with magnitude of 30g (15% dry weight of starch) is prepared and
83 added with 300mL distillate water and it is stirred by using *magnetic stirrer* at
84 3 scale; 200g starch is added while stirred; 5% NaOH is added while stirred
85 by using magnetic stirrer at 8 scale to prevent starch gelatinization and pH
86 level of solution is set at 10.5 and stirred for 30 minutes at room
87 temperature; The solution is incubated using shaker incubator at
88 temperature of 40±2°C (200rpm, 24 hours); POCl₃ is added 0.08%(w/w)
89 while stirred by using magnetic stirrer at 8 scale for 30 minutes and then
90 incubated at temperature of 40±2°C (200rpm, 2 hours); pH of solution is set
91 to 5.5 using 10% HCl solution to stop the reaction; Starch is sieved by
92 using Whatman paper no. 4 and washed with distillate water for 5 minutes.
93 Starch drying is done at temperature of 45°C for 6 hours to get starch with
94 water content of 10-12%.

95

96 *Protein extract preparation*

97 Procedure for protein extract from eel and its preparation for
98 addition into edible film is as follows (modified method of Heruwati and Jav,
99 1995): Eel is cleaned by discharging its head part and stomach content
100 followed by cleaning with clean water; Cutting operation is done to separate
101 flesh portion from bone and skin (*fillet*) followed by smashing of eel
102 flesh; Smash flesh is cleaned with cold water at temperature of about 1 to
103 5°C using water having volume 5 times of smash flesh volume for 10
104 minutes; Smash flesh is stirred within cold water until homogenous and is
105 stopped to precipitate smash flesh, whereas impurities and lipid are floating
106 in water surface, followed by discharging the impurities; Water is separated
107 from cleaned smash flesh by using pressing equipment; Smash flesh is
108 recleaned within cold water and added with 0.3% salt (w/v) at the third
109 cleaning and followed by recompressing to discharge water as much as
110 possible; 2% of sorbitol (w/v) is added and stirred until homogenous; Smash
111 flesh is freezed within *freezer* at temperature of about -15°C for 1 week;
112 Frozen smash flesh is thawed for 30 minutes followed by weighing with
113 magnitude of 2% (w/v), 4% (w/v) and 6% (w/v) from total aquadest volume;
114 100ml aquadest and NaOH 1 M are added to achieve pH 11 and stirred,
115 heated at temperature of 55°C for 30 minutes; Heating and screening of
116 suspension are done to produce protein extract; Reheated is done at
117 temperature 60°C; and solution (suspension) is ready to be used as edible
118 film material.
119

120 *Edible film preparation.*

121 Procedure for processing of canna starch edible film without and
122 with the addition of protein extract of eel is as follows: Preparation of canna
123 starch native (P_1) and (P_2) modified using $POCl_3$ 0,08% with magnitude of
124 4% (w/v); The addition of aquadest followed by stirring and sieving; Starch
125 suspension heating at gelatinization temperature of 65°C using *hot*
126 *plate* followed by stirring with *magnetic stirrer*; The slowly addition of
127 glycerol 3% (v/v) to starch suspension that had fully gelatinized and then
128 followed by heating for about 10 minutes; Addition of eel extract protein
129 according to treatments with concentration of S_1 (2%), S_2 (4%), and S_3 (6%)
130 v/v; Addition of CMC surfactant according to treatments with concentration
131 of 2% (b/v); Suspension is stirred until homogenous and addition of bees
132 wax with concentration of 1% (b/v); Removing dissolved gas (*degassing*) by
133 using vacuum pump for 1 hour; Pouring the 40mL of suspension to petri
134 dish 15cm in diameter followed by moulding and heating at 70°C for 12
135 hours using oven; and cooling at room temperature followed by edible film
136 removal from moulder and wrapped with plastics, put it into desiccator for
137 24 hours.

138

139 *Statistical analysis*

140 Statistical analysis on completely randomized experimental was
141 done by using SAS computer Program of Window 6.12 version. One-way
142 analyses of variance (ANOVA) were carried out and mean comparisons
143 were processed by Duncan test. Significance was defined as $p < 0.05$.

144

145 **Results and discussion**

146 Addition of protein extract of eel has an objective to improve
147 elongation degree of canna starch edible film. Protein molecules of eel
148 within edible film matrix is bound with hydrophilic components such as
149 starch, glycerol and CMC. Astiana (2012) had explained that eels contain
150 15.90% essential and non-essential hydrophobic proteins which consisted
151 of lysine and glutamic acid with magnitudes of 7.13g / 100g and
152 12.89g/100g, respectively.

153 Analysis of variance results showed that extract protein of eel
154 treatments had significant effect, whereas their interaction had no
155 significant effect on elongation percentage value of edible film ($\alpha=0.05$).
156 Results of Duncan test (Table 1) showed that elongation percentage value
157 of modified canna starch edible film was significantly different than that of
158 native canna starch edible film. Treatment 2% protein extract of eel was
159 significantly different than that of 4% and 6%, but treatment 4% protein
160 extract of eel was not significantly different than that of 6% in term of edible
161 film elongation percentage.

162 Elongation degree value of modified canna starch edible film
163 (57.33%) was higher than that of native canna starch edible film (48.00%).
164 This was due to the fact that modified canna starch had more open starch
165 molecules structure and low retrogradation characteristics. This starch
166 structure cause protein molecules of eel is easily enter to edible film matrix
167 and bound with hydrophilic components such as starch, glycerol and CMC.

168 Low retrogradation characteristics of modified canna starch cause protein
169 molecules of eel trapped and stable within edible film matrix.

170 According to Nakai and Modler (1999), protein extract of eel contain
171 the same protein such as found in fish, i.e. myofibrillar and sarcoplasmic
172 with magnitude of 65 to 75% and 20 to 30%, respectively. Weng *et al.*
173 (2007) had stated that myofibrillar protein has fibrous form and elastics
174 whereas sarcoplasmic protein is globular. Myofibrillar protein affect edible
175 film elasticity increment and sarcoplasmic protein decrease polymers
176 interaction and cohesive power of edible film matrix as well as produce
177 more flexible edible film. Fish protein based *edible film* consisting of
178 myofibrillar or sarcoplasmic protein generally have better mechanical
179 properties, especially flexibility property, but has low barrier to water vapour
180 transmission rate (Hamaguchi *et al.*, 2007)

181 Table 1 showed that higher protein extract of eel results in higher
182 elongation degree of *edible film*. Higher protein extract of eel results in
183 higher quantity of myofibrillar and sarcoplasmic protein molecules which
184 are trapped within edible film matrix.

185 Average value of elongation percentage of canna starch edible film
186 with protein extract of eel was higher than that of edible film without protein
187 extract (Figure 1). However, this edible film elongation percentage had not
188 fulfilled the stated standard of JIS 1975, i.e. minimum of 70% for all addition
189 levels of protein extract.

190 Analysis of variance results showed that protein extract of eel had
191 significant effect on edible film compressive strength value, whereas their

Comment [W4]: Please make it clear. The figure 1 can not confirm this statement. The treatment C2 (in figure 1) needs to be clearly defined in edible film preparation whether it is a control (treatment without addition of protein extract).

192 interaction was not significant ($\alpha=0.05$). Compressive strength value of
193 modified canna starch edible film was significantly different than to native
194 starch edible film. The use of protein extract of eel with concentrations of
195 2%, 4% and 6% gave significantly different values of edible film
196 compressive strength (Table 1).

197 Compressive strength value of modified canna starch edible film
198 was higher than native starch film. This was caused by stronger molecular
199 structure of canna starch modified than native. POCl_3 cross linked canna
200 starch had some substituted OH groups by phosphate. This substitution
201 increase the structural strength of starch molecules that resulted the
202 stronger starch molecules. Degree of edible film matrix strength is
203 increased by increasing starch strength.

204 Table 1 showed that the higher the protein extract concentration of
205 eel, the higher the compressive strength of edible film. This was due to the
206 fact that protein extract of eel contains myofibrillar protein. This protein
207 molecular chains have fibrous form and length. Higher myofibrillar protein
208 content results in more compact edible film and higher resistance power to
209 pressure. This results was in accordance to study that reported by Sobralet
210 *et al.* (2005) which showed that the use of 2g of myofibrillar protein in 100g film
211 solution had higher pressure strength than that of 1g myofibrillar protein in
212 100g film solution. Artharn *et al.* (2008) had stated that edible film
213 formulation with ratio myofibrillar protein and sarcoplasmic protein of 10:0
214 had produced the highest value of compressive strength.

215 Compressive strength value of canna starch edible film with protein
 216 extract of eel was lower than that without protein extract addition (Figure 2).
 217 Sarcoplasmic protein is globular form protein. This protein is dispersed
 218 amongst edible film matrix which lower interaction with film matrix polymers
 219 and lower compactness which subsequently decrease the edible film
 220 resistance power to pressure. Artharn *et al.* (2008) had reported that
 221 compressive strength of protein-based edible film will decrease when
 222 concentration of sarcoplasmic protein is increase.

223 Analysis of variance results showed that treatments of protein
 224 extract of eel had significant effect on water vapour transmission rate of
 225 edible film ($\alpha=0,05$). Results of Duncan test (Table 1) showed that
 226 treatments of 2%, 4% and 6% protein extract of eel had significant effect on
 227 water vapour transmission rate of edible film.

228 Table 1 showed that higher protein concentration had produced
 229 lower water vapour transmission rate. This was due to protein extract of eel
 230 which had myofibrillar and sarcoplasmic proteins. Molecular structure of
 231 myofibrillar protein is consisted of fibrous molecular chains. The higher the
 232 concentration of protein extract of eel, the higher the quantity of myofibrillar
 233 protein which in turn produce more solid and compact of film matrix
 234 structure. This condition impede water vapour to penetrate edible film
 235 matrix. Shiku *et al.* (2003) had added that water vapour transmission rate of
 236 edible film produced from myofibrillar protein was relatively lower than that
 237 of edible films produced from other proteins. Sarcoplasmic proteins are
 238 globular proteins containing most of the hydrophobic and SH groups hidden

Comment [W5]: Please make it clear. The figure 2 can not confirm this statement. The treatment C2 (in figure 2) needs to be clearly defined in edible film preparation whether it is a control (treatment without addition of protein extract).

239 in the interior of molecules. Formation of sarcoplasmic protein films
240 prepared from blue marlin (*Makairamazara*) has mainly involved thermal
241 treatment of film-forming solutions at temperature ranging between 55°C
242 and 90°C (Iwata *et al.*, 2000).

243 Figure 3 showed that water vapour transmission rate of canna
244 starch edible film with protein extract of eel was higher than that without
245 protein extract of eel. This was due to protein molecules as structural
246 components of edible film matrix which has hydrophilic characteristics.
247 Protein addition results in increase of hydrophilic components within edible
248 film matrix. Therefore, the higher the hydrophilic components, the easier the
249 water vapour to penetrate edible film. Yoshida *et al.* (2002) described that
250 natural hydrophilic property of protein in edible film formulation facilitate the
251 interaction with water which lower edible film resistance power to water
252 vapour. Nayak *et al.* (2008) described that protein-based edible film was
253 very effective as barrier to oxygen gas and aroma, but this edible film
254 showed relatively high value of water vapour transmission rate.

255

256 Conclusion

257 Addition of eel's protein extract had increased elongation
258 percentage and decreased water vapour transmission rate of edible film.
259 Compressive strength of edible film had decreased with eel's protein extract
260 addition, but addition of higher concentration of eel protein extracts had
261 increased its compressive strength.

334 Table 1. Results of Duncan test for the effect of eel's protein extract on
 335 elongation percentage, compressive strength and water vapour transmission
 336 rate of canna's starch edible film.

337

Treatment	Elongation percentage (%)	Compressive Strength (Newton)	Water vapour transmission rate (g.m ⁻² .d ⁻¹)
S ₁	47.60 ^a	51.69 ^a	22.60 ^a
S ₂	51.67 ^b	58.17 ^b	21.68 ^b
S ₃	58.84 ^b	63.87 ^c	18.85 ^c

338 *Remarks:* Numbers followed by the same letter in the same column are not
 339 significantly different at 5% level of Duncan test
