

Figure 1. In Vitro Rumen Degradation of Dry Matter

Figures 2 and 3 show the patterns of rumen degradation of NDF and ADF. It can be seen that with the exception of NDF degradation of *F. macrophylla*, the degradabilities of NDF and ADF were not significantly different among the species of legumes. However, after 24 hr incubation period, there was a tendency that *C. pubescens* had higher NDF degradation values. Consistent with dry matter, both NDF and ADF degradation values of *F. macrophylla* were relatively lower than those of other legumes. These differences were due primarily to a lower undegraded fraction, and are likely to be the result of differences in the phenological fiber characteristics of *F. macrophylla* and the other legumes.

Table 2. In Vitro Rumen Degradation Characteristics of Dry Matter, NDF, ADF and Cellulose

Item	72 h*	a	b	a+b	C

A,b,c,d : p<0.05

The pattern of rumen degradability of cellulose is given in Figure 4. At 72 hr incubation period, rumen degradability of cellulose varied from 52.50% (*D. virgatus*) to 57.14% (*C. pubescens*). Furthermore, the rate of cellulose degradation was highest for *L. leucocephala* (0.045 fract./hr), followed by *C. pubescens* (0.039 fract./hr).
