

Determination of prioritization for maintenance of the upper structure of truss bridge

Heni Fitriani^{1*}, M. Ade Surya Pratama¹, Yakni Idris¹, and Gunawan Tanzil¹

¹Department of Civil Engineering, Universitas Sriwijaya, Palembang, Indonesia

Abstract. Bridge maintenance is one of the major issues of infrastructure problems. Deterioration of a bridge's structure will continuously increase without proper maintenance. This condition will adversely affect the service life of a bridge. Moreover, the damage will also have a direct impact on structural and functional failure of the bridge. This paper aims at identifying the damages of truss bridges and determining the most significant criteria and sub-criteria used in prioritizing bridge maintenance. Analytical Hierarchy Process (AHP) was used to assess the most important criteria that give significant weight to bridge maintenance analysis. The objects of research were nine truss bridges with a wide range of types and levels of damage. It was found that there were approximately 900 m' of components damaged at the railing of Baruga Bridge and 227 m' truss damages due to poor quality of the galvanized paint. Furthermore, based on the analysis, the most significant criteria were the level of damage (27.6%), the technical aspects (25.7%), the finance (21%), the vehicle load (13.6%) and the resources (12%). The results of this research showed important findings in determining the priority scales for bridge repair and maintenance systems.

1 Introduction

The role of the bridge in the transportation system is very strategic and crucial to link any roadway network as well as control the movement of its traffic. Due to the function and safety of the road, the existence of the bridge should have special attention for its structural and functional condition for reliability and serviceability. The maintenance of bridges plays an essential role in reassuring the service and dependability of the bridge network. Thus, it is necessary to define a reliable strategy for maintaining and rehabilitating the bridge.

Studies on bridge maintenance have been emerging for many decades [1, 5-9]. According to Hasan et al. [5], the inspection and condition rating of the bridge has significantly affected the decisions for further action of bridge maintenance. This study also addressed the deterioration forecast of bridge components using visual inspection data and proposed the deterioration trends for its structural elements. Gattuli & Chiamonte [4] studied the condition assessment using visual inspection and developed modules for bridge inventory, computer visual inspection, and priority ranking procedure. Wang & Elhaq [10]

*Corresponding author: heni.fitriani@unsri.ac.id

combined the Analytical Hierarchy Process (AHP) and Data Envelopment Analysis (DEA) to assess risks of bridge elements for decision making. Meanwhile, Walia et al. [11] presented the damage evaluation of truss bridge using the deflection test.

To maintain the condition of the bridges, there is a need to develop condition assessment to prioritize the bridge components as well as to propose the bridge maintenance procedures. Continuous damage over time will increase the maintenance cost. It is known that there are limited funds available for maintenance. Thus, the bridge required a priority to prepare the maintenance program of the bridge. The purpose of this research is to identify damages along with their volume for each bridge and to determine the most significant criteria and sub-criteria for a bridge maintenance program. AHP was used to measure the most dominant criteria in fulfilling the maintenance selection program on truss frame bridge and determine the priority scale of bridge handling.

2 Methodology

This paper adopted the Bridge Management System [2, 3] to establish the criteria for bridge assessment. The bridge condition was determined by a series of assessment criteria based on the hierarchy process of the bridge structure. The bridge assessors evaluated the terms based on their experience, values, and knowledge. This assessment was done during the bridge inspection. The condition ratings are in between 1-9 which reflect the bridge condition values and the elements at a given time. Each element of the bridges consists of these following aspects as seen in Table 1. Five criteria were used to assess the condition of bridges comprising of structure condition, damage level, damage volume, element functions, and element effects to the damages.

Table 1. Scale of condition ratings for AHP.

Intensity interest	Description
1	Equal importance
3	Weak importance of one over another
5	Essential or strong importance
7	Demonstrated importance
9	Absolute importance
2, 4, 6, 8	Intermediate values between the two adjacent judgments

The primary objective of this paper is to identify the damages of the upper structure of bridges and to determine the most significant criteria in prioritizing bridge maintenance. Analytical Hierarchy Process (AHP) was used to assess the most important criteria that give the significant weights to the bridge maintenance analysis. AHP used multiple criteria analysis by taking account of more than one criterion.

Field surveys were conducted to record the damage characteristics of each bridge structure accurately. The data were used to plan a bridge-handling program. The investigation was carried out by directly monitoring 9 (nine) truss frame bridges located in South Sumatra Province. The survey team consisted of an inspector and two assistant inspectors. The inspector was in charge of verifying the damages to the upper building in accordance with the truss frame bridge hierarchy and putting the notes to the form when the

survey took place. The questionnaires were then distributed to selected respondents based on the expertise, knowledge, and experience in the field of bridges. The respondents consisted of 12 respondents from the National Road Implementation Agency V (BBPJV), three respondents from the Public Works of South Sumatra Province, and two respondents from the consultant and academia. Therefore, the number of respondents in total were 17 people.

The inspection was carried out using the standards used in the Bridge Management System. Criteria of assessment were undertaken at each level can be seen in Fig. 1.

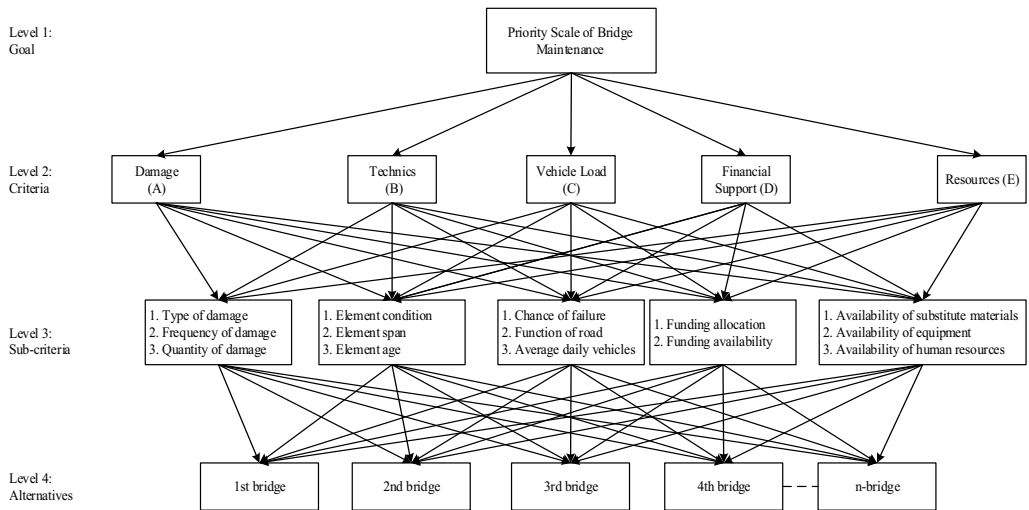

Fig. 1. Hierarchy of prioritizing the bridge maintenance.

Table 2. Descriptions of bridges.

Name of bridge	Build year	Length (m)
Baruga	1985	227
Ketapang	1999	16
Air Kelingi	1990	100
Sekambil	2000	40.2
Penyambungan	2000	45.5
Petudung	1999	40
Arau Besar	1999	40
Air Batu	1999	40
Musi Lakitan	1985	120

The inspection procedures were performed by systematically checking the relevant bridges from the truss to the equipment and recording the elements along with the damage, the location of the defective component and its condition value on the inspection form. The element condition was determined based on a survey by recording the periodic inspection along with the detail damages. The assessment of conditions was intended to assess the

extent of damage conditions that occur in the structure to sub-elements of the bridge at a certain time. The assessment of the state of truss frame bridge elements was put into a detailed checking form.

The objects of research were nine truss-frame bridges with a wide range of types and levels of damage conditions element as shown in Table 2. The detailed criteria and sub-criteria were given in the table. Baruga and Musi Lakitan bridges were built in 1985, Sekambil and Penyambungan in 2000, and the remaining were constructed between 1985 and 2000. It is known that Baruga Bridge has the longest among those nine bridges.

3 Results and discussion

One of the complex issues facing the entire bridge is the damage to the buildings of the bridge due to several factors that influence it. Elements/sub-elements of mild or severe damage were reported in the form of a list of damage which might help the decision makers prepare the plans and bridge management program. The results of field surveys provide information on the type, the extent and the amount of damage that occur in each element or sub-element of a steel truss bridge. The lists of damage are used to determine the type of treatment and to calculate the necessary budget plan in the handling of the bridge.

The condition assessment on the upper structure of 9 truss bridges was conducted. However, only three bridges are explained in this paper. The damage cases were assessed on each element to identify the types and volume of the damages as shown in Table 3. The list of damages was described regarding the kind of damage, level, and magnitude of damages in every element of the upper structure of 9 truss bridges. The upper elements consist of the truss, running surface, deck joint, bearing, and railing. It was found that there were approximately 900 m' of components damaged at the railing of Baruga Bridge and 227 m' truss damages due to the decrease in the quality of the galvanized paint. Similarly, Air Kelingi Bridge had around 800 m² of cracks on the surface layer of the running surface. Meanwhile, Air Batu bridge had the least damages for all parts of the upper structure of the bridge elements.

Fig. 2. Damage measurement on truss bridge.

Analytical Hierarchy Process (AHP) has been widely used as a comprehensive decision-making method. AHP generates a set of alternative criteria and options to make the best decision. In this paper, AHP was used to prioritize the most significant criteria and sub-criteria. The weights of criteria were determined based on the assessment of the respondents for each criterion and sub-criteria as seen in Table 4. The matrices of options were then calculated before finalizing the ranking options. Moreover, the consistency index and consistency ratio were also checked. Table 4 indicated the ratio of each criterion from 17 respondents. Matrix B-A is a reciprocal matrix A-B as shown in Eq. 1 below. The summary of matrices is shown in Table 5.

$$\text{Matrices B-A} = \frac{1}{(A-B)} = 1/0.79 = 1.27 \quad (1)$$

Table 3. Types of damage and volumes for bridge elements.

No	Bridges	Elements of bridge	Types of damages	Volume	Unit
1	Baruga	Truss	Poor quality of the galvanized paint	227	m'
			Corrosion in truss elements	227	m'
		Running surface	Pipe and drainage of the clogged floor	61	each
			Perforated and cracked surface layer	45	m ²
		Deck joint	Loose parts / loose bond	18	m ²
		Railing	Poor quality of the galvanized paint	14.26	m ²
Damaged / missing components	908		m'		
2	Ketapang	Truss	Poor quality of the galvanized paint	16	m'
		Running surface	Hole/ crack/ rough on the sidewalk	0.02	m ²
		Deck joint	Connection loss damage	12	m ²
		Bearing	A flawed foundation	4	each
		Railing	Poor quality of the galvanized paint	1.01	m ²
			Damaged / missing components	64	m'
3	Air Kelingi	Truss	Poor quality of the galvanized paint	100	m'
			Corrosion in truss elements	100	m'
		Running surface	Pipe and drainage of the clogged floor	40	each
			Perforated and cracked surface layer surface layer	800	m ²
			Hole / crack / rough on the sidewalk	0.40	m ²
		Deck joint	Loose parts / loose bond	240	m'
Railing	Poor quality of the galvanized paint	6.28	m ²		

$$\begin{aligned}
 \text{Matrices AA} &= ((\text{matrix AA} \times \text{matrix AA}) + (\text{matrix AB} \times \text{matrix BA}) + (\text{matrix AC} \times \text{matrix CA}) + (\text{matrix AD} \times \text{matrix DA}) + (\text{matrix AE} \times \text{matrix EA})) \quad (2) \\
 &= ((1.00 \times 1.00) + (0.79 \times 1.27) + (3.43 \times 0.29) + (0.88 \times 1.14) + (2.54 \times 0.39)) \\
 &= 5.00
 \end{aligned}$$

$$\begin{aligned}
 \text{Row A} &= \text{matrix AA} \times \text{matrix AB} \times \text{matrix AC} \times \text{matrix AD} \times \text{matrix AE} \quad (3) \\
 &= (5.00 \times 6.75 \times 10.96 \times 6.85 \times 13.06) \\
 &= 42.61
 \end{aligned}$$

Eigen vector can be defined as follows:

$$W_i = \sqrt[n]{\text{number of rows; } n \text{ for matrix} = 5 \times 5} \quad (4)$$

$$W_i \text{ row A} = \sqrt[5]{42.61} = 2.12$$

$$\text{Eigen vector } (X_i) = W_i / \sum W_i = 2.12 / 9.84 = 0.276 \quad (5)$$

Table 6. The Eigen value.

Criteria	A	B	C	D	E	Sum	W _i	E-Vector
A	5.00	6.75	10.96	6.85	13.06	42.61	2.12	0.276
B	5.69	5.00	11.11	6.63	11.27	39.71	2.09	0.257
C	2.86	3.38	5.00	3.91	5.91	21.05	1.84	0.136
D	4.08	4.63	9.00	5.00	9.68	32.38	2.00	0.210
E	2.67	2.73	4.64	3.54	5.00	18,58	1.79	0.120
Σ	20.30	22.49	40.70	25.92	44.91	154.32	9.84	1.00

$$\text{Eigen value max } (\lambda \text{ maximum}) = \Sigma a_{ij} \cdot X_j \quad (6)$$

$$= 5.262 \text{ (see Table 6).}$$

Consistency Index (CI) and Consistency Ratio (CR) were also calculated using Eq. 7 and 8:

$$\text{Consistency index (CI)} = \frac{\lambda \text{ max} - n}{n - 1} = \frac{(5.262 - 5)}{(5 - 1)} = 0.066 \quad (7)$$

$$\text{Consistency ratio (CR)} = \frac{CI}{RI} = \frac{0.066}{1.12}, \text{ where RI} = 1.12 \quad (8)$$

$$= 0.059 < 0.1 \text{ Consistent!}$$

The summary of the analysis was presented in Table 7 and 8. It can be seen that the most significant criteria were the level of damage (27.6%), technical aspects (25.7%), finance (21%), vehicle load (13.6%) and resources (12%). The results of this research showed the essential findings in determining the priority scales for bridge repair and maintenance systems.

Table 7. Summary of criteria and the weights.

Criteria	Weights
Damage (A)	0.276
Technicals (B)	0.257
Vehicle Load (C)	0.136
Financial Support (D)	0.210
Resources (E)	0.120
Total	1.00

Table 9 also exhibited the weights of each criterion as well as the rank of prioritization for bridge maintenance for nine bridges. It can be concluded that the first five (5) priorities of bridges to maintain from deterioration were shown by the highest amount of weights

namely Air Kelingi (84.6%), Musi Lakitan (75.1%), Ketapang (66.2%), Sekambil (66.2%), and Arau Besar (64.7%).

Table 8. Weights for each criterion.

No	Criteria	Weight	Sub-criteria	Weight	Criteria weight (%)
1	Damage	0.276	Type of damage	0.272	7.50
			Frequency of damage	0.290	8.01

			Availability of equipment	0.350	4.22
			Availability of human resource	0.237	2.86

4 Conclusions

This paper aims at defining the most significant criteria and sub-criteria used in prioritizing bridge maintenance. Analytical Hierarchy Process (AHP) was used to assess the most important criteria that give the significant weights to the bridge maintenance analysis. The objects of research were nine truss-frame bridges with a wide range of types and levels of damage. The types of damages, as well as the quantity of the damages, were identified on nine bridges on each bridge element. It was found that the most significant criteria were the level of damage (27.6%), technical aspects (25.7%), finance (21%), traffics (13.6%) and resources (12%). The results of this research showed the important findings in determining the priority scales for bridge repair and maintenance systems. It was also found that the first five (5) priorities of bridges to maintain from deterioration were shown by the highest amount of weights, namely Air Kelingi (84.6%), Musi Lakitan (75.1%), Ketapang (66.2%), Sekambil (66.2%), and Arau Besar (64.7%). This paper presented the ways in determining scale priority of bridge maintenance using case study. Further research is needed to consider other criteria in the assessment of bridge maintenance.

Table 9. Summary of weights of each criterion and rank of bridge priority for maintenance.

No	Name of bridges	Weights of each criterion														Weights	Weights (%)	Rank of prioritization
		Damage (a)			Technical aspects (b)			Vehicle load (c)			Financial support (d)		Resources (e)
